13.1 The Problem

It was a real triumph to design a compiler that understood expressions such as

$$(x + y) * \exp(x - z) - 4.0$$
$$a * b + c/d - c * (x + y)$$
$$!(p \ \&\& \ q) \ || \ (x \leq 7.0)$$

In fact, the name FORTRAN stands for

FORMula TRANslator

13.1.1 The Quadratic Formula

$$x = (-b + (b^2 - 4ac)^{\frac{1}{2}}) / (2a)$$

13.2.2 Polish Notation

Hence the complete prefix form for the quadratic formula is

$= \ x \ / \ + \ \sim \ b \ \uparrow \ - \ \uparrow \ b \ 2 \ \times \ \times \ 4 \ a \ c \ \frac{1}{2} \ \times \ 2 \ a.$

You should verify yourself that the postfix form is

$x \ b \ \sim \ b \ 2 \ \uparrow \ 4 \ a \ \times \ c \ \times \ - \ \frac{1}{2} \ \uparrow \ + \ 2 \ a \ \times \ / \ =.$

13.3.4 Evaluation of Postfix Expressions

- Scan postfix expression from left to right pushing operands on to a stack.
- When an operator is encountered, pop as many operands as this operator needs; evaluate the operator; push the result on to the stack.
- This works because, in postfix, operators come immediately after their operands.

Postfix Evaluation

- $(a + b) * (c - d) / (e + f)$
- $a\ b +\ c\ d -\ *\ e\ f +\ /$
- $a\ b +\ c\ d -\ *\ e\ f +\ /$
- $a\ b +\ c\ d -\ *\ e\ f +\ /$
- $a\ b +\ c\ d -\ *\ e\ f +\ /$
