Chapter 4 Network Layer

KUROSE ROSS

A note on the use of these ppt slides:

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we' d like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

Network Layer 4

Assignments (ver6,中文/英文):

ch4: 1, 7, 9, 11, 13, 16, 19, 26, 30, 37, 39, 42,
52, 53

Chapter 4: network layer

chapter goals:

- understand principles behind network layer services:
 - network layer service models
 - forwarding versus routing
 - how a router works
 - routing (path selection)
 - broadcast, multicast
- instantiation, implementation in the Internet

Chapter 4: outline

4.1 introduction

- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

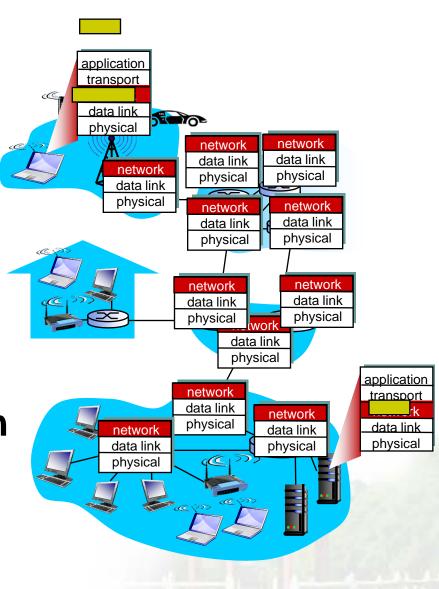

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Network layer

 transport segment from sending to receiving host

 on sending side encapsulates segments into datagrams

- on receiving side, delivers segments to transport layer
- network layer protocols in every host, router
- router examines header fields in all IP datagrams passing through it

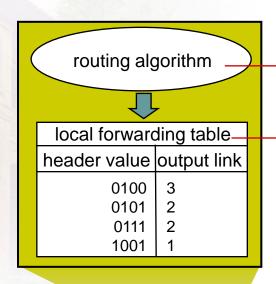

Two key network-layer functions

- routing: determine route taken by packets from source to dest.
 - routing algorithms
- forwarding: move packets from router's input to appropriate router output
- Connection Setup
 - Not included in IP

analogy:

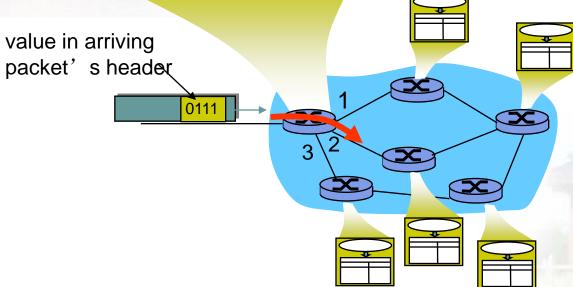

- routing: process of planning trip from source to dest
- forwarding: process of getting through single interchange

Interplay between routing and forwarding

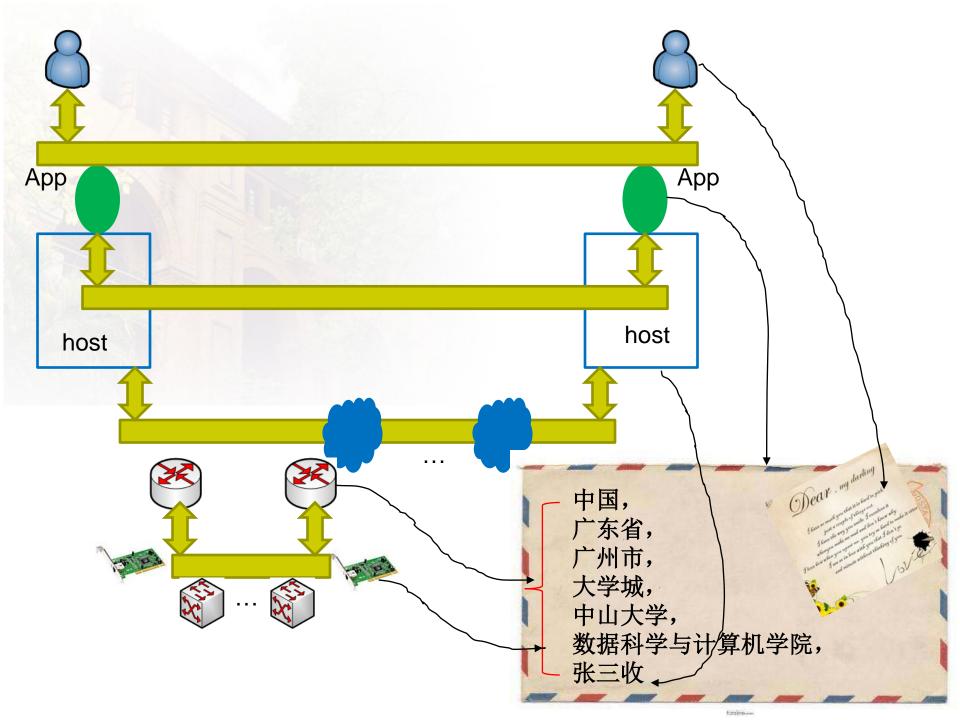

routing algorithm determines end-end-path through network

forwarding table determines local forwarding at this router

Connection setup

- 3rd important function in some network architectures:
 - ATM, frame relay, X.25
- before datagrams flow, two end hosts and intervening routers establish virtual connection
 - routers get involved
- network vs transport layer connection service:
 - network: between two hosts (may also involve intervening routers in case of VCs)
 - transport: between two processes

Network service model

Q: What service model for "channel" transporting datagrams from sender to receiver?

example services for individual datagrams:

- guaranteed delivery
- guaranteed delivery with less than 40 msec delay

example services for a flow of datagrams:

- in-order datagram delivery
- guaranteed minimum bandwidth to flow
- restrictions on changes in inter-packet spacing

Network layer service models:

Network	Service Model	Guarantees ?				Congestion
Architecture		Bandwidth	Loss	Order	Timing	feedback
Internet	best effort	none	no	no	no	no (inferred via loss)
ATM	CBR	constant rate	yes	yes	yes	no congestion
ATM	VBR	guaranteed rate	yes	yes	yes	no congestion
ATM	ABR	guaranteed minimum	no	yes	no	yes
ATM	UBR	none	no	yes	no	no

UBR: Unspecified Bit Rate VBR: Variable Bit Rate

CBR: Constant Bit Rate

ABR: Available Bit Rate

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Connection, connection-less service

- * datagram network provides network-layer connectionless service
- virtual-circuit network provides network-layer connection service
- * analogous to TCP/UDP connection-oriented / connectionless transport-layer services, but:
 - service: host-to-host
 - no choice: network provides one or the other
 - implementation: in network core

Virtual circuits

"source-to-dest path behaves much like telephone circuit"

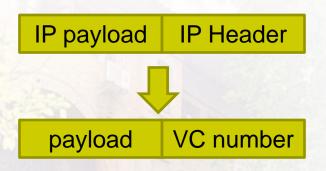

- performance-wise
- network actions along source-to-dest path
- call setup, teardown for each call before data can flow
- each packet carries VC identifier (not destination host address)
- every router on source-dest path maintains "state" for each passing connection
- link, router resources (bandwidth, buffers) may be allocated to VC (dedicated resources = predictable service)

VC implementation

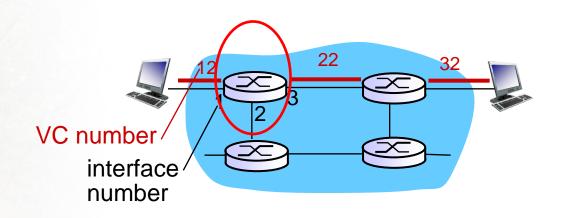

a VC consists of:

- 1. path from source to destination
- 2. VC numbers, one number for each link along path
- 3. entries in forwarding tables in routers along path
- packet belonging to VC carries VC number (rather than dest address)
- VC number can be changed on each link.
 - new VC number comes from forwarding table

VC forwarding table

forwarding table in northwest router:

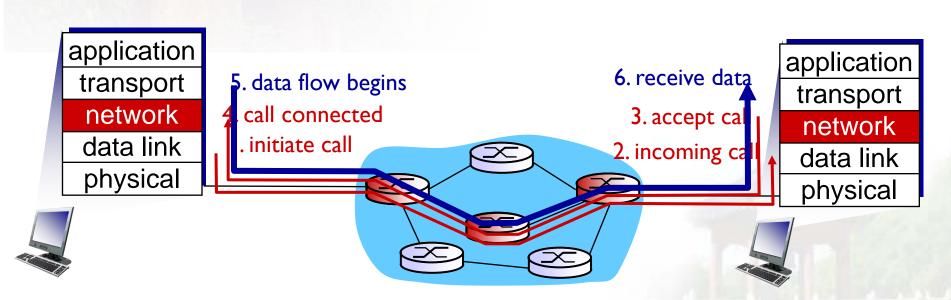

Incoming interface	Incoming VC #	Outgoing interface	Outgoing VC #
1	12	3	22
2	63	1	18
3	7	2	17
1	97	3	87
•••		•••	111
			Zill Hill Hard

VC routers maintain connection state information!

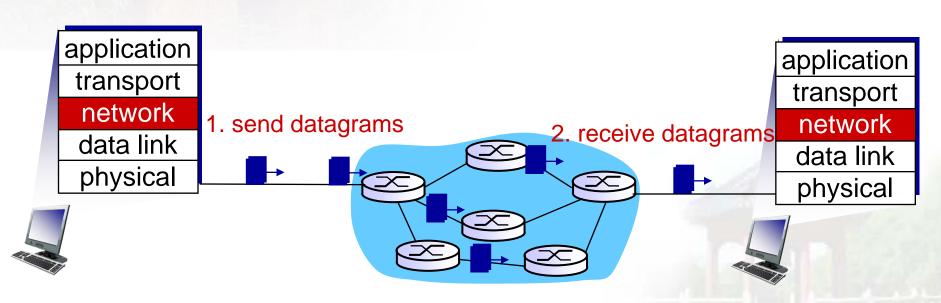

Virtual circuits: signaling protocols

- used to setup, maintain teardown VC
- used in ATM, frame-relay, X.25
- not used in today's Internet

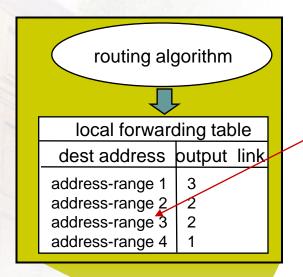

Datagram networks

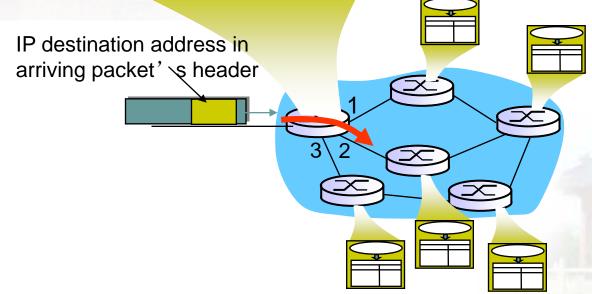

- no call setup at network layer
- routers: no state about end-to-end connections
 - no network-level concept of "connection"
- packets forwarded using destination host address

Datagram forwarding table

4 billion IP addresses, so rather than list individual destination address list range of addresses (aggregate table entries)

Datagram forwarding table

Destination Address Range				Link Interface
11001000 through	00010111	00010000	0000000	0
11001000	00010111	00010111	11111111	
11001000 through	00010111	00011000	0000000	1
	00010111	00011000	11111111	·
11001000 through	00010111	00011001	0000000	2
11001000	00010111	00011111	11111111	
otherwise				3

Q: but what happens if ranges don't divide up so nicely?

Longest prefix matching

longest prefix matching

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination Address Range	Link interface
11001000 00010111 00010*** ******	0
11001000 00010111 00011000 *****	1
11001000 00010111 00011*** *****	2
otherwise	3

examples:

DA: 11001000 00010111 00010110 10100001

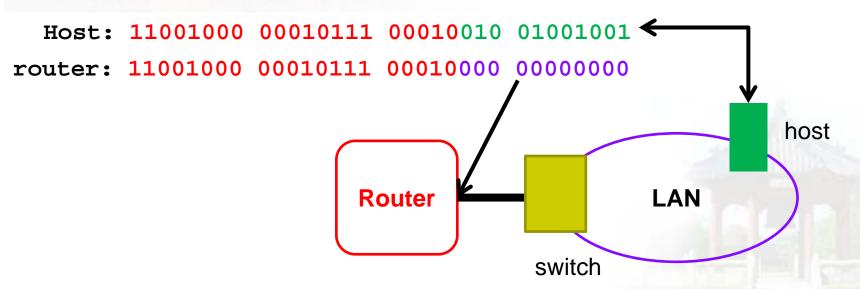

DA: 11001000 00010111 00011000 10101010

which interface? which interface?

Destination Address Range			Link interface	
11001000 through	00010111	00010000	0000000	0
	00010111	00010111	11111111	

Destination Address Range	Link interface
11001000 00010111 00010*** ******	0

Datagram or VC network: why?

Internet (datagram)

- data exchange among computers
 - "elastic" service, no strict timing req.
- many link types
 - different characteristics
 - uniform service difficult
- "smart" end systems (computers)
 - can adapt, perform control, error recovery
 - simple inside network, complexity at "edge"

ATM (VC)

- evolved from telephony
- human conversation:
 - strict timing, reliability requirements
 - need for guaranteed service
- "dumb" end systems
 - telephones
 - complexity inside network

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

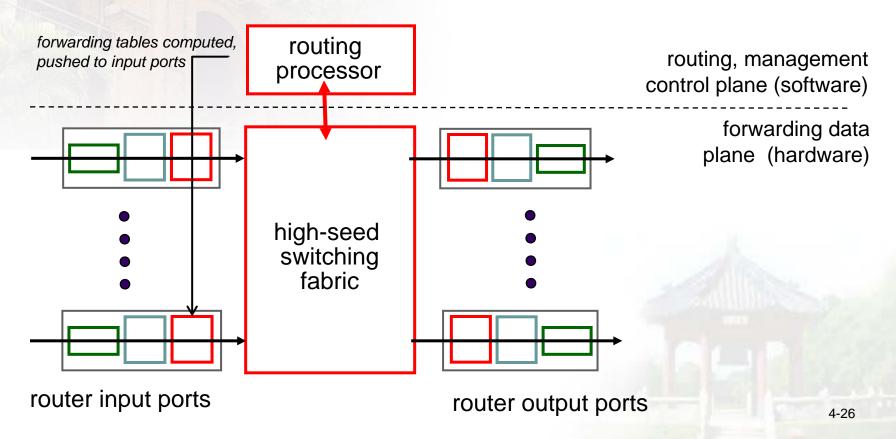

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

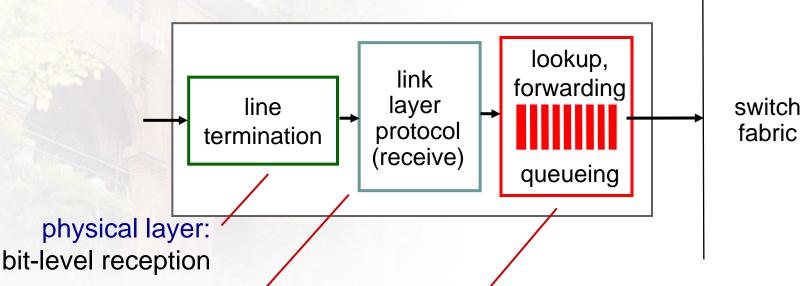

Router architecture overview

two key router functions:

- run routing algorithms/protocol (RIP, OSPF, BGP)
- forwarding datagrams from incoming to outgoing link

Input port functions

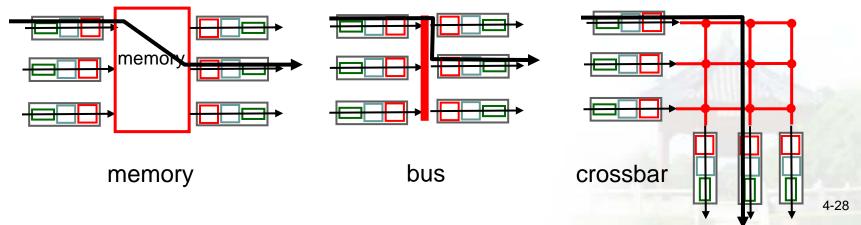

data link layer: e.g., Ethernet see chapter 5

decentralized switching:

- given datagram dest., lookup output port using forwarding table in input port memory ("match plus action")
- goal: complete input port processing at 'line speed'
- queuing: if datagrams arrive faster than forwarding rate into switch fabric

Switching fabrics

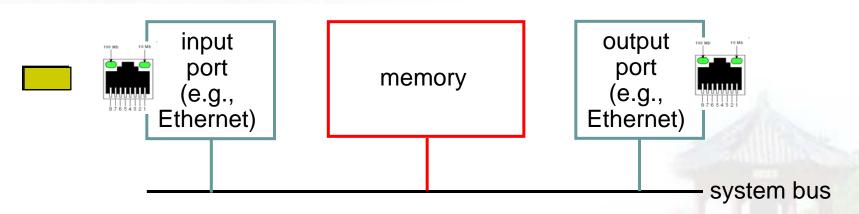

- * transfer packet from input buffer to appropriate output buffer
- * switching rate: rate at which packets can be transfer from inputs to outputs
 - often measured as multiple of input/output line rate
 - N inputs: switching rate N times line rate desirable
- three types of switching fabrics

Switching via memory

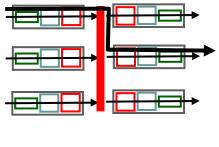

first generation routers:

- traditional computers with switching under direct control of CPU
- packet copied to system's memory
- speed limited by memory bandwidth (2 bus crossings per datagram)

Switching via a bus

- datagram from input port memory
 to output port memory via a shared bus
- bus contention: switching speed limited by bus bandwidth
- 32 Gbps bus, Cisco 5600: sufficient speed for access and enterprise routers

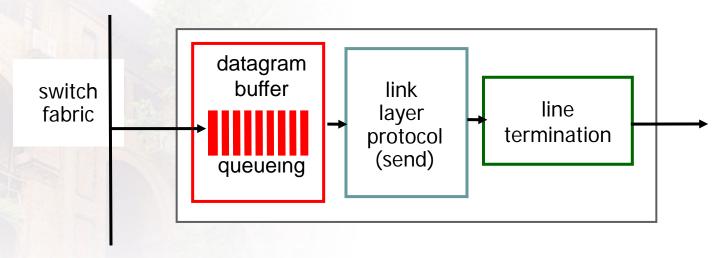

bus

Switching via interconnection network

- overcome bus bandwidth limitations
- banyan networks, crossbar, other interconnection nets initially developed to connect processors in multiprocessor
- advanced design: fragmenting datagram into fixed length cells, switch cells through the fabric.
- Cisco 12000: switches 60 Gbps through the interconnection network

crossbar

Output ports

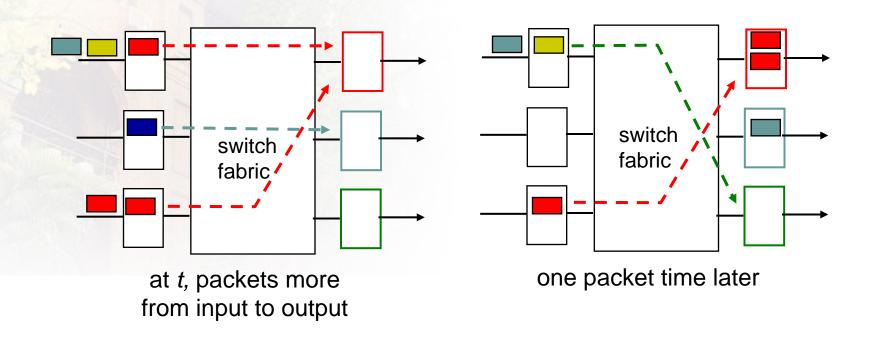

* buffering required from fabric faster

Datagram (packets) can be lost due to congestion, lack of buffers

 scheduling discipline chooses among queued datagrams for transmission

Priority scheduling – who gets best performance, network neutrality

Output port queueing

- buffering when arrival rate via switch exceeds output line speed
- queueing (delay) and loss due to output port buffer overflow!

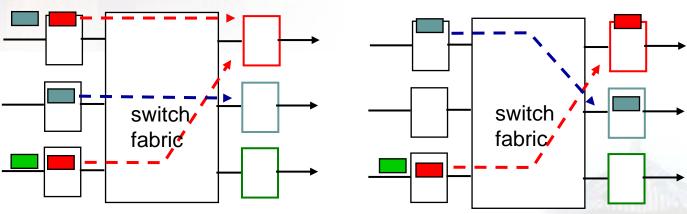

How much buffering?

- RFC 3439 rule of thumb: average buffering equal to "typical" RTT (say 250 msec) times link capacity C
 - e.g., C = 10 Gpbs link: 2.5 Gbit buffer
- recent recommendation: with N flows, buffering equal to

$$\frac{\mathsf{RTT} \cdot \mathsf{C}}{\sqrt{\mathsf{N}}}$$

Input port queuing

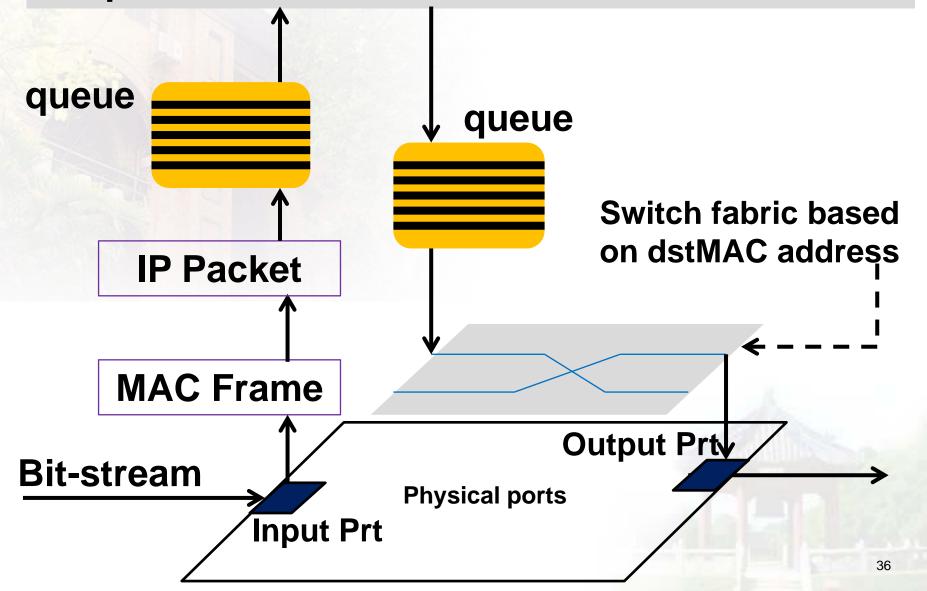

- fabric slower than input ports combined -> queueing may occur at input queues
 - queueing delay and loss due to input buffer overflow!
- Head-of-the-Line (HOL) blocking: queued datagram at front of queue prevents others in queue from moving forward

output port contention:
only one red datagram can be
transferred.
lower red packet is blocked

one packet time later:
green packet
experiences HOL
blocking

- 1. Routing algorithm based on dstIP
- 2. Update dstMAC address for next device

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

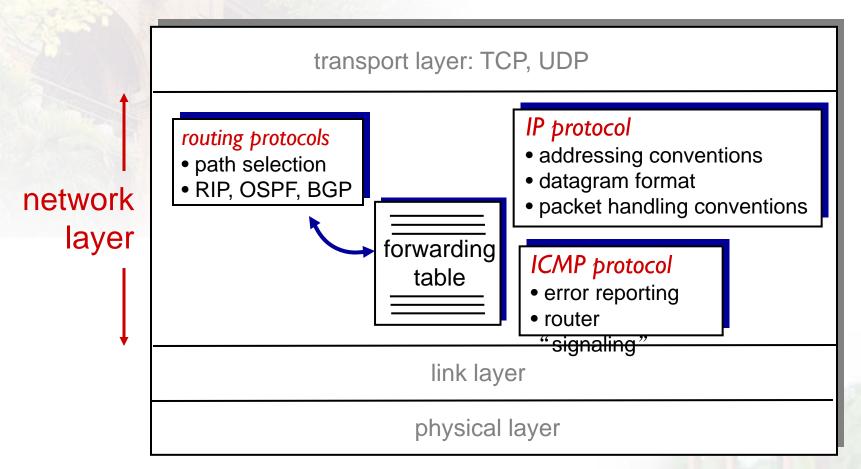

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

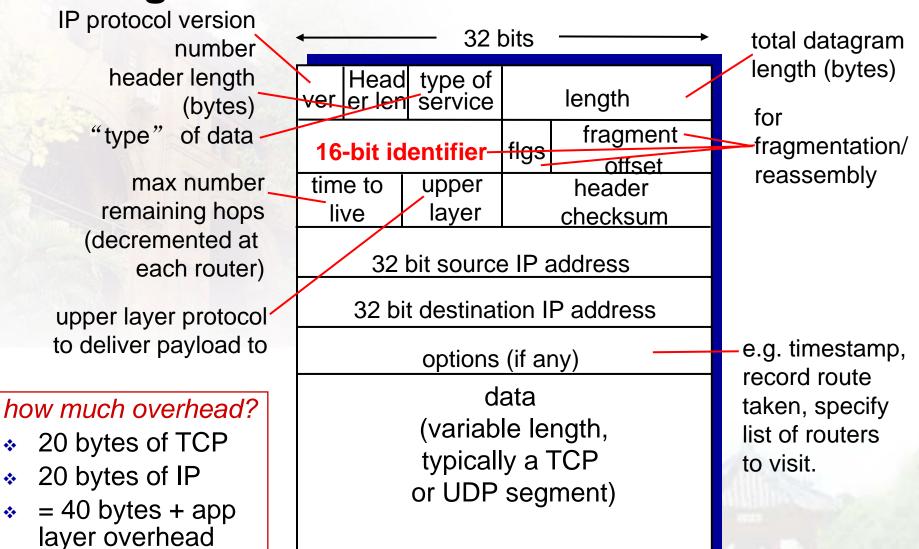

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

The Internet network layer

host, router network layer functions:

IP datagram format

"16-bit identifier" is NOT a number for reordering No reordering in Net Layer

IP fragmentation, reassembly

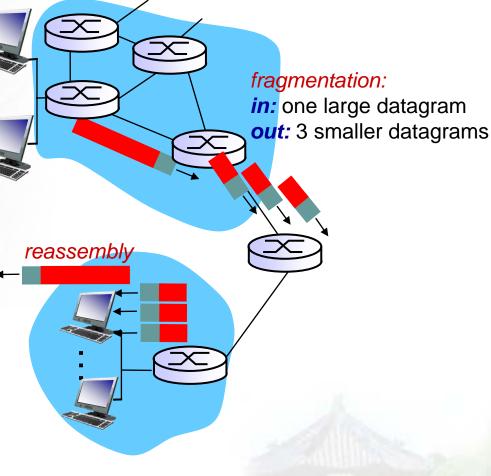

network links have MTU (max.transfer size) - largest possible link-level frame

 different link types, different MTUs

 large IP datagram divided_ ("fragmented") within net

one datagram becomes several datagrams

- "reassembled" only at final destination
- IP header bits used to identify, order related fragments

IP fragmentation, reassembly

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- **4.4 IP: Internet Protocol**
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

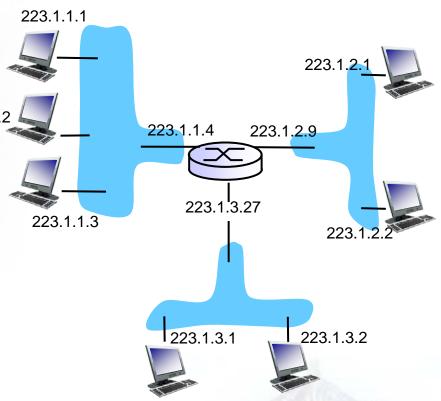

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

IP addressing: introduction

- IP address: 32-bit identifier for host, router interface
- interface: connection²²³
 between host/router and physical link
 - Router's typically have multiple interfaces
 - host typically has one or two interfaces (e.g., wired Ethernet, wireless 802.11)
- IP addresses associated 223.1.1.1 = 11011111 00000001 00000001 00000001 with each interface 223 1 1 1 1

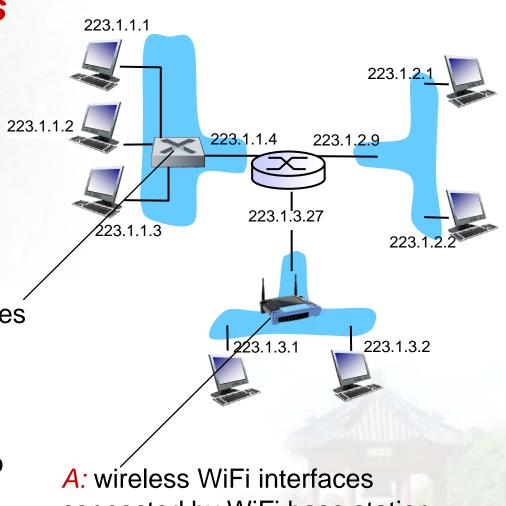

IP addressing: introduction

Q: how are interfaces actually connected?

A: we'll learn about that in chapter 5, 6.

A: wired Ethernet interfaces connected by Ethernet switches

For now: don't need to worry about how one interface is connected to another (with no intervening router)

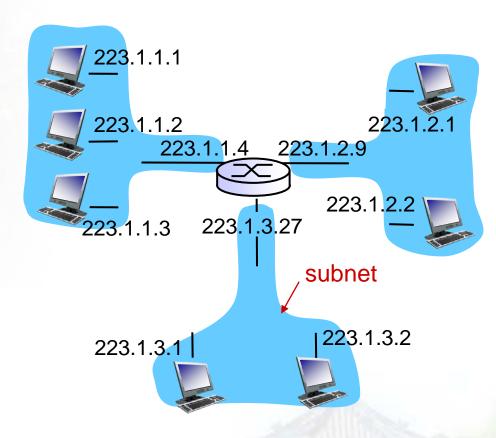

connected by WiFi base station

Subnets

• IP address:

- subnet part high order bits
- host part low order bits
- what's a subnet?
 - device interfaces with same subnet part of IP address
 - can physically reach each other without intervening router

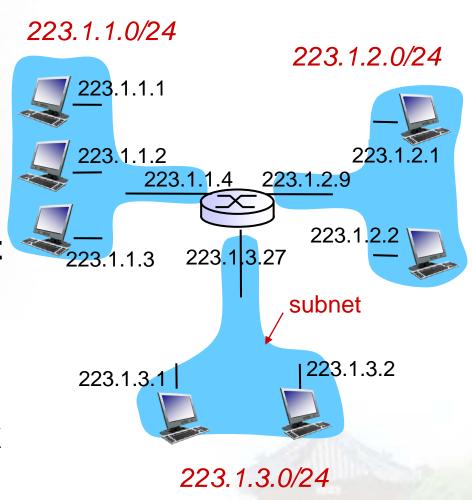

network consisting of 3 subnets

Subnets

recipe

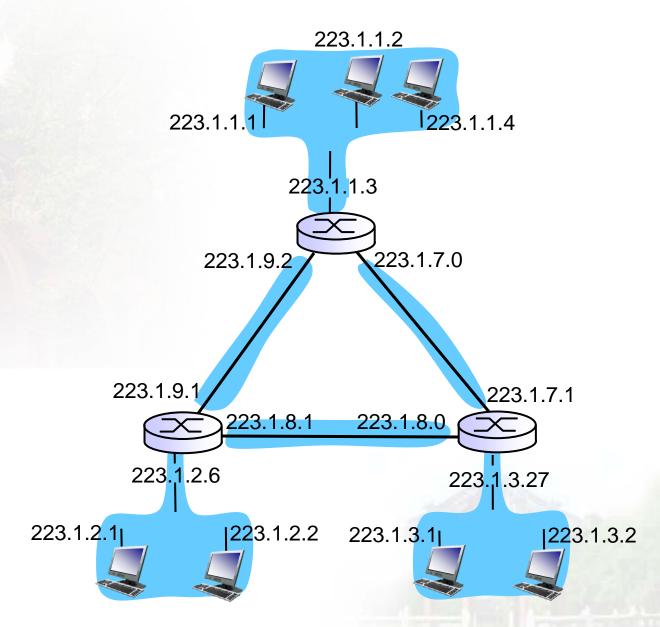

- to determine the subnets, detach each interface from its host or router, creating islands of isolated networks
- each isolated network is called a subnet

subnet mask: /24

Subnets

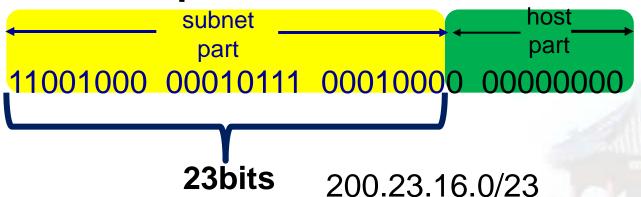

how many?

IP addressing: CIDR

CIDR: Classless InterDomain Routing

- subnet portion of address of arbitrary length
- address format: a.b.c.d/x, where x is # bits in subnet portion of address

How to route an IP?

Router gets an IP with dstIP 11001000 00010111 00010110 10100001

Match it with forwarding table: 11001000 00010111 00010000 00000000/21

11001000 10010111 00010000 00000000/22

11001000 10010111 00010000 00000000/15

•••

forwarding

IP addresses: how to get one?

Q: How does a host get IP address?

hard-coded by system admin in a file

- Windows: control-panel->network->configuration->tcp/ip->properties
- UNIX: /etc/rc.config
- DHCP: Dynamic Host Configuration Protocol: dynamically get address from as server
 - "plug-and-play"

DHCP: Dynamic Host Configuration Protocol

goal: allow host to dynamically obtain its IP address from network server when it joins network

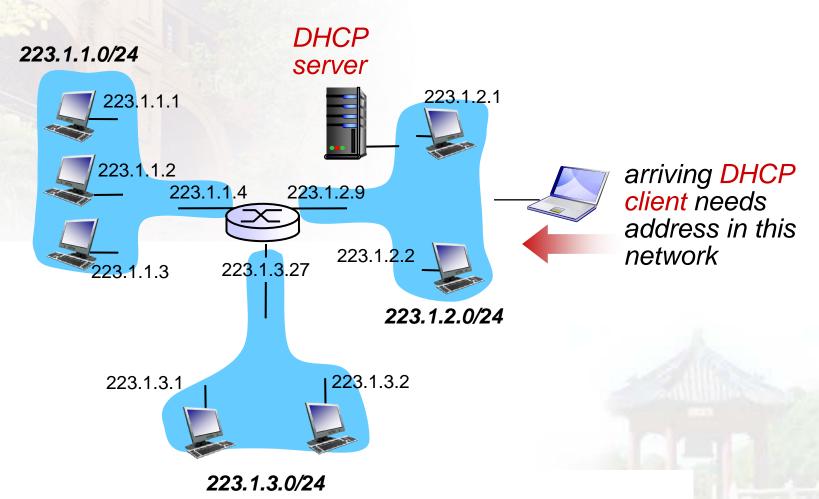

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/"on")
- support for mobile users who want to join network (more shortly)

DHCP overview:

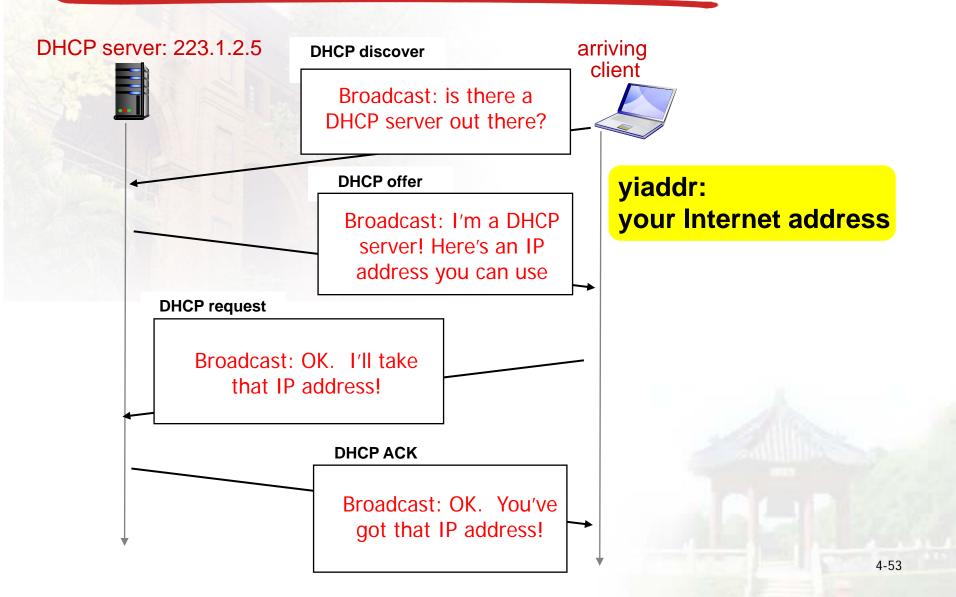

- host broadcasts "DHCP discover" msg [optional]
- DHCP server responds with "DHCP offer" msg [optional]
- host requests IP address: "DHCP request" msg
- DHCP server sends address: "DHCP ack" msg

4-51

DHCP client-server scenario

DHCP client-server scenario

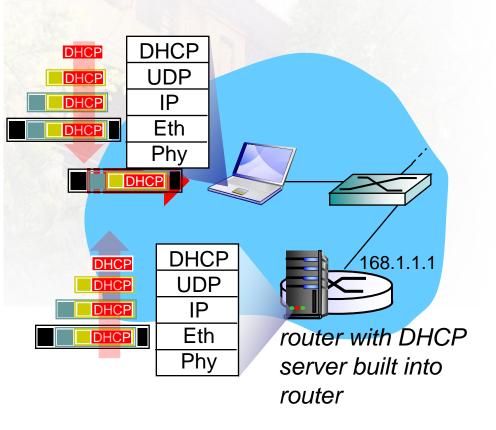

DHCP: more than IP addresses

DHCP can return more than just allocated IP address on subnet:

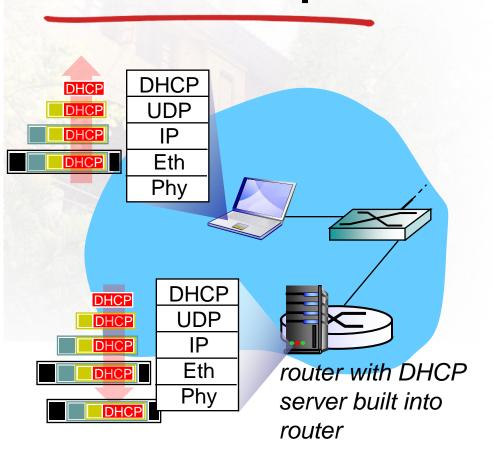

- address of first-hop router for client
- name and IP address of DNS sever
- network mask (indicating network versus host portion of address)

DHCP: example

- connecting laptop needs its IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.1 Ethernet
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

DHCP: example

- DCP server formulates
 DHCP ACK containing
 client's IP address, IP
 address of first-hop router
 for client, name & IP
 address of DNS server
- encapsulation of DHCP server, frame forwarded to client, demuxing up to DHCP at client
- client now knows its IP address, name and IP address of DSN server, IP address of its first-hop router

DHCP: Wireshark output (home LAN)

reply

IP addresses: how to get one?

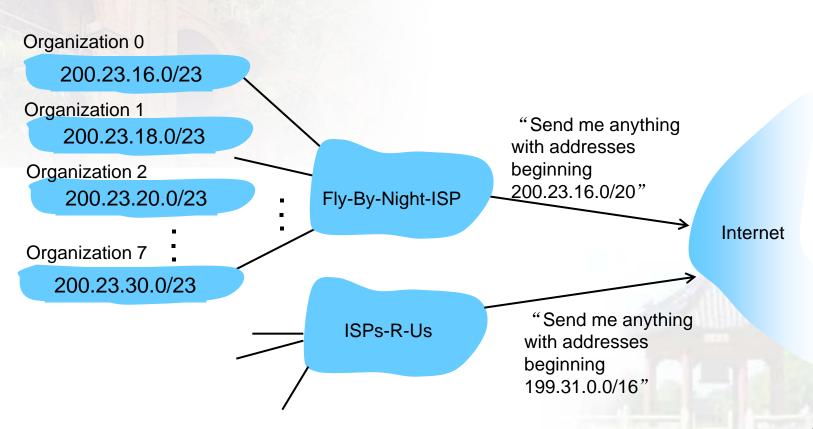

Q: how does network get subnet part of IP addr?

A: gets allocated portion of its provider ISP's address space

ISP's block	11001000	00010111	0001	00000000	200.23.16.0/20
Organization 0 Organization 1	11001000	00010111	0001 <mark>0000</mark>	00000000	200.23.16.0/ <mark>23</mark> 200.23.18.0/23
Organization 2	11001000	00010111	00010010	00000000	200.23.16.0/23
Organization 7	11001000	00010111	00011110	00000000	200.23.30.0/23

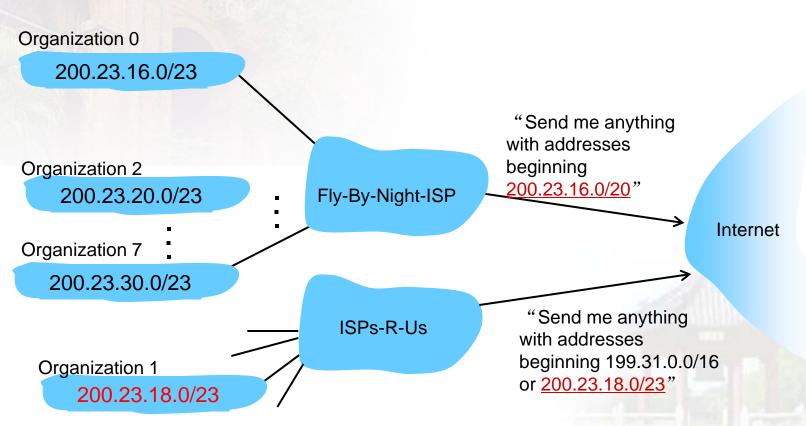

Hierarchical addressing: route aggregation

hierarchical addressing allows efficient advertisement of routing information:

Hierarchical addressing: more specific routes

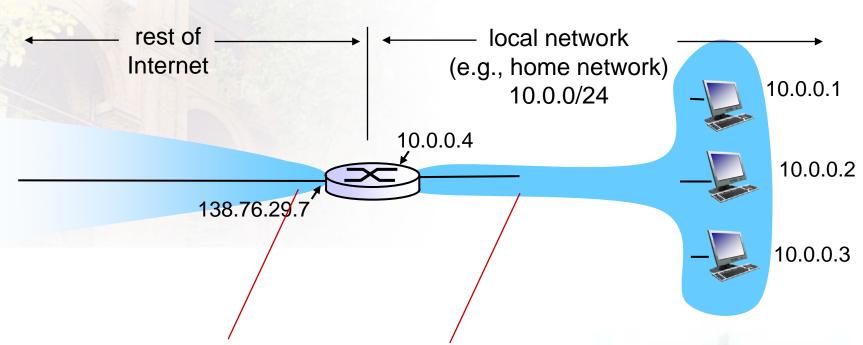

ISPs-R-Us has a more specific route to Organization I

IP addressing: the last word...

- Q: how does an ISP get block of addresses?
- A: ICANN: Internet Corporation for Assigned Names and Numbers http://www.icann.org/
 - allocates addresses
 - manages DNS
 - assigns domain names, resolves disputes

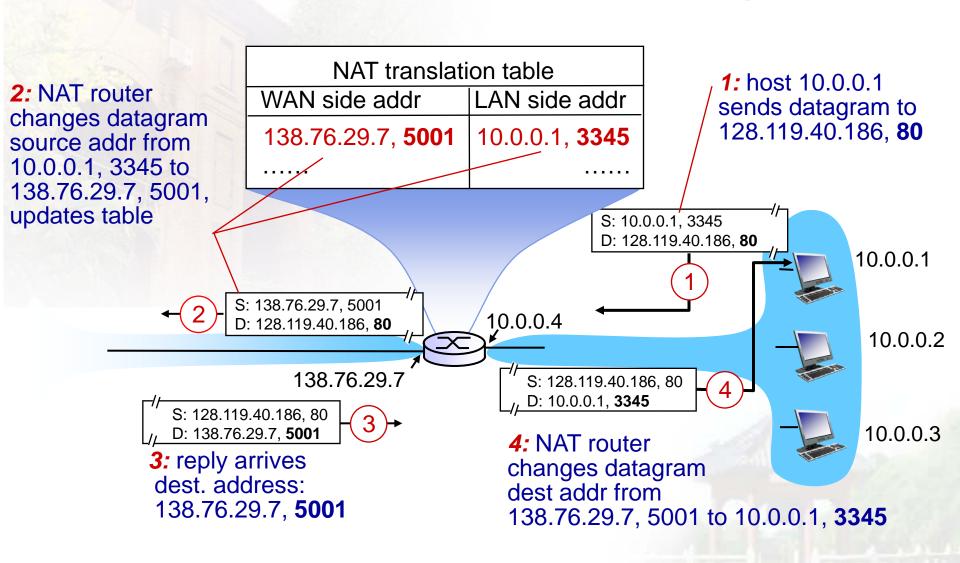

Week 11

all datagrams leaving local network have same single source NAT IP address: 138.76.29.7, different source port numbers datagrams with source or destination in this network have 10.0.0/24 address for source, destination (as usual)

motivation: local network uses just one IP address as far as outside world is concerned:

- range of addresses not needed from ISP: just one IP address for all devices
- can change addresses of devices in local network without notifying outside world
- can change ISP without changing addresses of devices in local network
- devices inside local net not explicitly addressable, visible by outside world (a security plus)

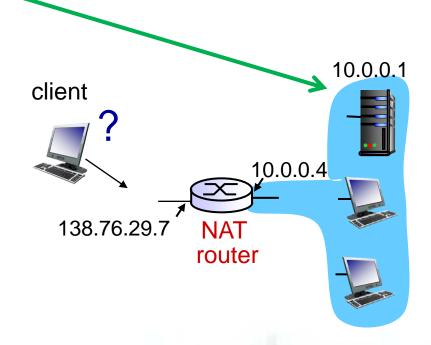

implementation: NAT router must:

- outgoing datagrams: replace (source IP address, port #) of every outgoing datagram to (NAT IP address, new port #)
 - ... remote clients/servers will respond using (NAT IP address, new port #) as destination addr
- remember (in NAT translation table) every (source IP address, port #) to (NAT IP address, new port #) translation pair
- incoming datagrams: replace (NAT IP address, new port #) in dest fields of every incoming datagram with corresponding (source IP address, port #) stored in NAT table

- 16-bit port-number field:
 - 60,000 simultaneous connections with a single LAN-side address!
- NAT is controversial:
 - routers should only process up to layer 3
 - violates end-to-end argument
 - NAT possibility must be taken into account by app designers, e.g., P2P applications
 - address shortage should instead be solved by IPv6

NAT traversal problem

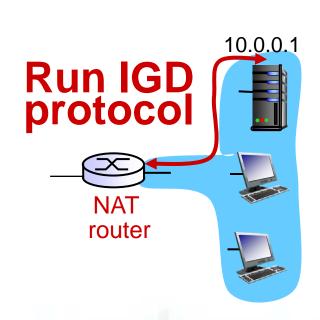

- client wants to connect to server with address 10.0.0.1
 - server address 10.0.0.1 local to LAN (client can't use it as destination addr)
 - only one externally visible NATed address: 138.76.29.7
- solution1: statically configure NAT to forward incoming connection requests at given port to server
 - e.g., (123.76.29.7, port 2500)always forwarded to 10.0.0.1 port 25000

NAT traversal problem

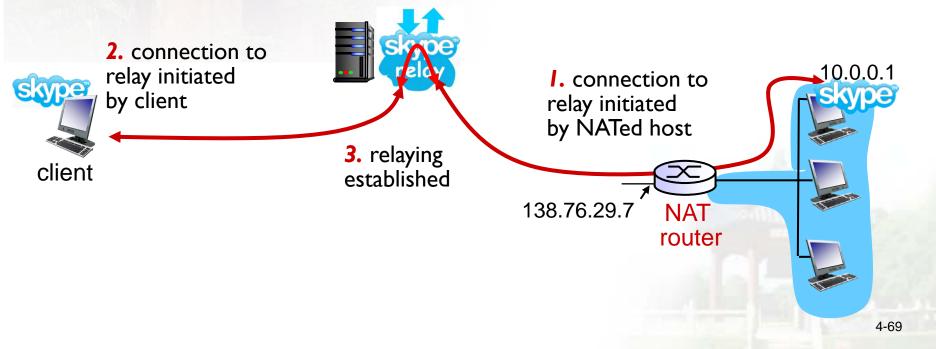

- solution 2: Universal Plug and Play (UPnP) Internet Gateway Device (IGD) Protocol. Allows NATed host to:
 - learn public IP address (138.76.29.7)
 - add/remove port mappings (with lease times)

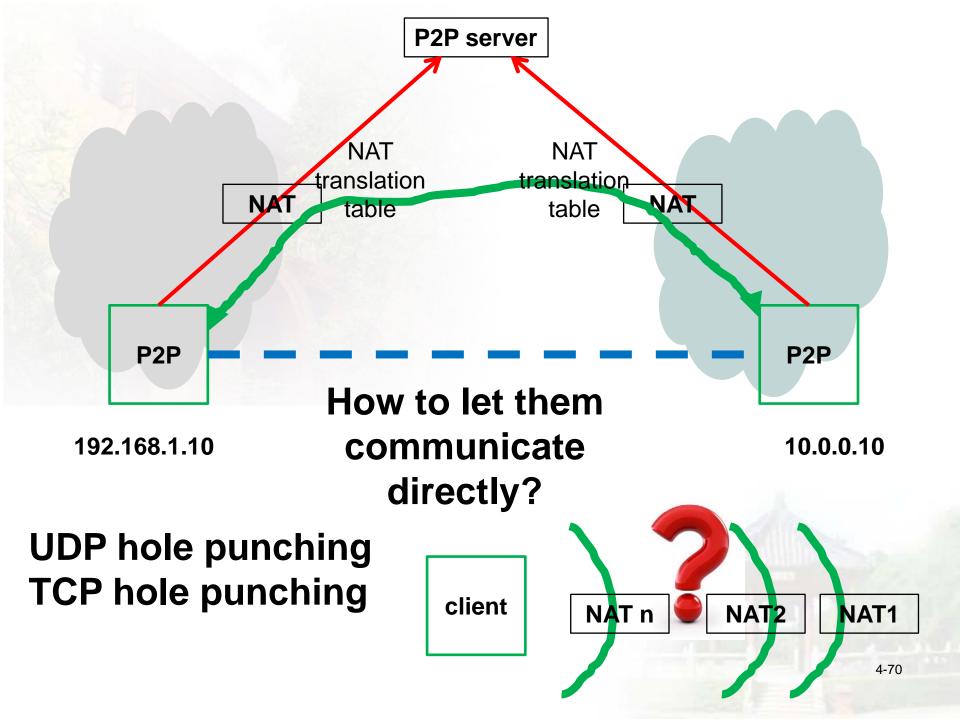

i.e., automate static NAT port map configuration

NAT traversal problem

- solution 3: relaying (used in Skype)
 - NATed client establishes connection to relay
 - external client connects to relay
 - relay bridges packets between to connections

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- **4.4 IP: Internet Protocol**
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

ICMP: internet control message protocol

- used by hosts & routers to communicate network-level information
 - error reporting: unreachable host, network, port, protocol
 - echo request/reply (used by ping)
- network-layer "above" IP:
 - ICMP msgs carried in IP datagrams
- ICMP message: type, code plus first 8 bytes of IP datagram causing error

<u>Type</u>	Code	description
0	0	echo reply (ping)
3	0	dest. network unreachable
3	1	dest host unreachable
3	2	dest protocol unreachable
3	3	dest port unreachable
3	6	dest network unknown
3	7	dest host unknown
4	0	source quench (congestion
		control - not used)
8	0	echo request (ping)
9	0	route advertisement
10	0	router discovery
11	0	TTL expired
12	0	bad IP header

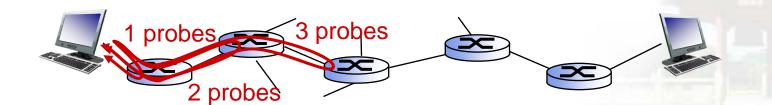

Traceroute and ICMP

- source sends series of UDP segments to dest
 - first set has TTL =1
 - second set has TTL=2, etc.
 - unlikely port number
- when nth set of datagrams arrives to nth router:
 - router discards datagrams
 - and sends source ICMP messages (type 11, code 0)
 - ICMP messages includes name of router & IP address

 when ICMP messages arrives, source records RTTs

stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops

IPv6: motivation

- initial motivation: 32-bit address space soon to be completely allocated.
- additional motivation:
 - header format helps speed processing/forwarding
 - header changes to facilitate QoS

IPv6 datagram format:

- fixed-length 40 byte header
- no fragmentation allowed

IPv6 datagram format

priority: identify priority among datagrams in flow flow Label: identify datagrams in same "flow." (concept of "flow" not well defined). next header: identify upper layer protocol for data

ver	pri	flow label		
payload len			next hdr	hop limit
source address (128 bits)				
destination address (128 bits)				
data				

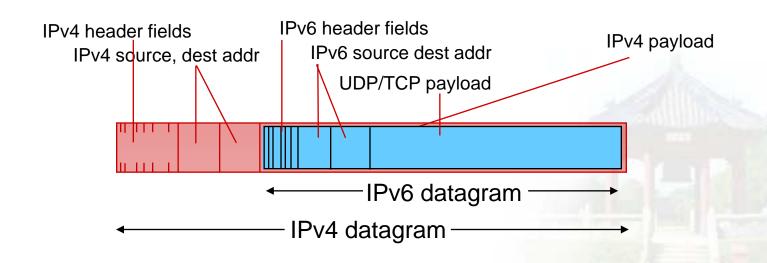

32 bits

Other changes from IPv4

- checksum: removed entirely to reduce processing time at each hop
- options: allowed, but outside of header, indicated by "Next Header" field
- ICMPv6: new version of ICMP
 - additional message types, e.g. "Packet Too Big"
 - multicast group management functions

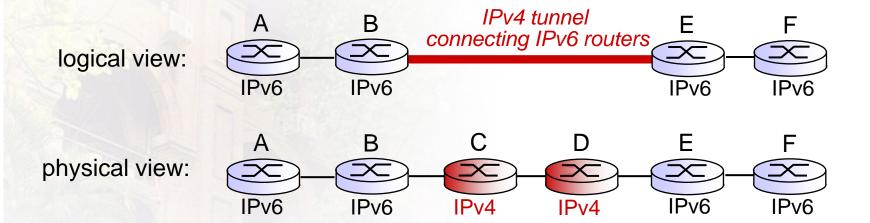

Transition from IPv4 to IPv6

- not all routers can be upgraded simultaneously
 - no "flag days"
 - how will network operate with mixed IPv4 and IPv6 routers?
- tunneling: IPv6 datagram carried as payload in IPv4 datagram among IPv4 routers

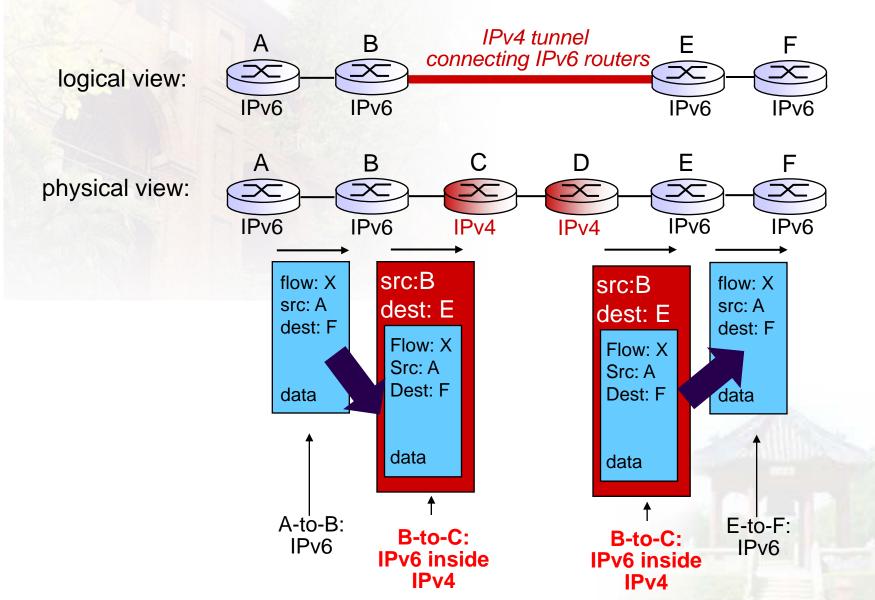

4-77

Tunneling

Tunneling

IPv6: adoption

- US National Institutes of Standards estimate [2013]:
 - ~3% of industry IP routers
 - ~11% of US gov't routers
- Long (long!) time for deployment, use
 - 20 years and counting!
 - think of application-level changes in last 20 years: WWW, Facebook, ...
 - Why?

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

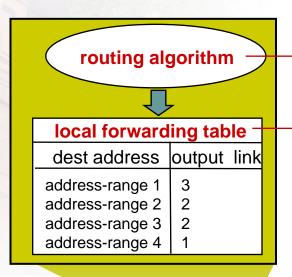

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

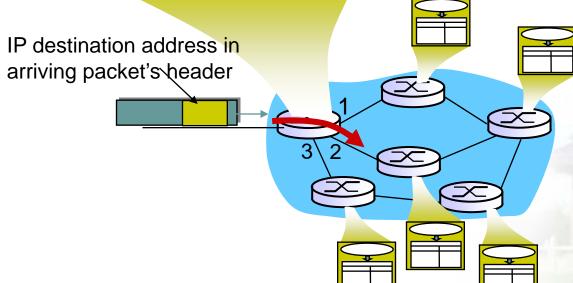

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Interplay between routing, forwarding

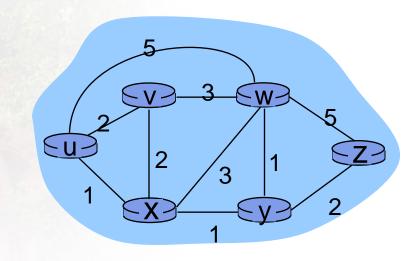

routing algorithm determines end-end-path through network

forwarding table determines local forwarding at this router

Graph abstraction

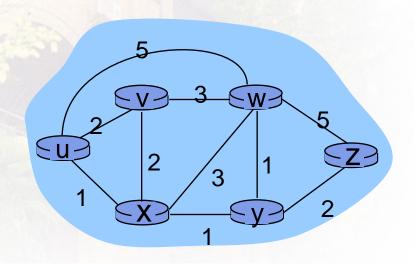

graph: G = (N,E)

 $N = set of routers = \{ u, v, w, x, y, z \}$

 $E = set of links = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

aside: graph abstraction is useful in other network contexts, e.g., P2P, where N is set of peers and E is set of TCP connections

Graph abstraction: costs

$$c(x,x') = cost of link (x,x')$$

e.g., $c(w,z) = 5$

cost could always be 1, or inversely related to bandwidth, or inversely related to congestion

cost of path
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

key question: what is the least-cost path between u and z? routing algorithm: algorithm that finds that least cost path

Routing algorithm classification

Q: global or decentralized information?

global:

- all routers have complete topology, link cost info
- "link state" algorithms

decentralized:

- router knows physicallyconnected neighbors, link costs to neighbors
- iterative process of computation, exchange of info with neighbors
- "distance vector" algorithms

Q: static or dynamic?

static:

routes change slowly over time

dynamic:

- routes change more quickly
 - periodic update
 - in response to link cost changes

Week442

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

A Link-State Routing Algorithm

Dijkstra's algorithm

- net topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- computes least cost paths from one node ('source") to all other nodes
 - gives forwarding table for that node
- iterative: after k iterations, know least cost path to k dest.'s

notation:

- c(x,y): link cost from node x to y; = ∞ if not direct neighbors
- D(v): current value of cost of path from source to dest.
- p(v): predecessor node along path from source to v
- N': set of nodes whose least cost path definitively known

Dijsktra's Algorithm

```
Initialization:
2 N' = \{u\}
  for all nodes v
     if v adjacent to u
       then D(v) = c(u,v)
5
6
    else D(v) = \infty
   Loop
    find w not in N' such that D(w) is a minimum
10 add w to N'
    update D(v) for all v adjacent to w and not in N':
12
      D(v) = \min(D(v), D(w) + c(w,v))
13 /* new cost to v is either old cost to v or known
    shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

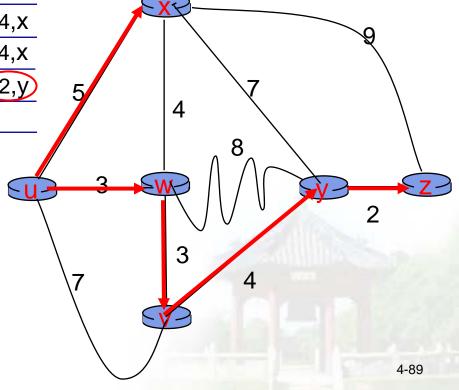

Dijkstra's algorithm: example

Find the least cost paths between u and other nodes

		D(v)	D(w)	D(x)	D(y)	D(z)
Ste	p N '	p(v)	p(w)	p(x)	p(y)	p(z)
0	u	7,u	3,u	5,u	∞	∞
1	uw	6,w		5,u	11,W	∞
2	uwx	6,w			11,W	14,X
3	uwxv				10,7	14,X
4	uwxvy					(12,y)
5	uwxvyz					

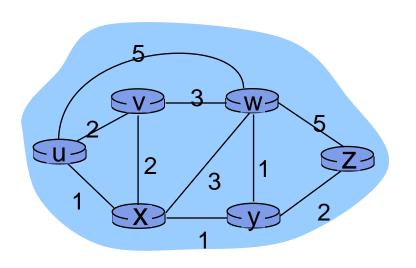

notes:

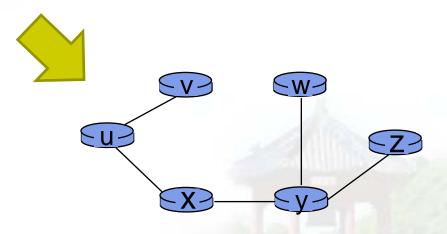

- construct shortest path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

Dijkstra's algorithm: another example

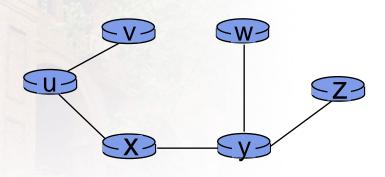

Step	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
0	u	2,u	5,u	1,u	∞	∞
1	ux ←	2,u	4,x		2,x	∞
2	uxy∙	2,u	3,y			4,y
3	uxyv		3,y			4,y
4	uxyvw ←					4,y
5	uxvvwz ←					

Dijkstra's algorithm: example (2)

resulting shortest-path tree from u:

resulting forwarding table in u:

destination	link
V	(u,v)
X	(u,x)
у	(u,x)
W	(u,x)
Z	(u,x)

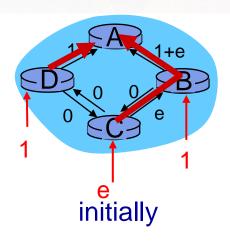

Dijkstra's algorithm, discussion

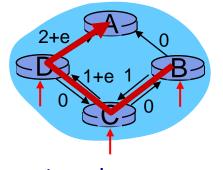

algorithm complexity: n nodes

- * each iteration: need to check all nodes, w, not in N
- n(n+1)/2 comparisons: O(n²)
- more efficient implementations possible: O(nlogn)

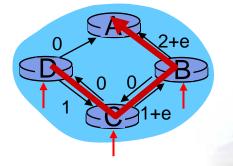

oscillations possible:

e.g., support link cost equals amount of carried traffic:

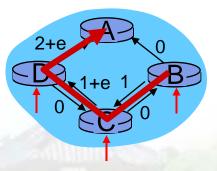

given these costs, find new routing.... resulting in new costs

given these costs, find new routing....

given these costs, find new routing.... resulting in new costs resulting in new costs

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Bellman-Ford equation (dynamic programming)

let

$$d_x(y) := cost of least-cost path from x to y$$

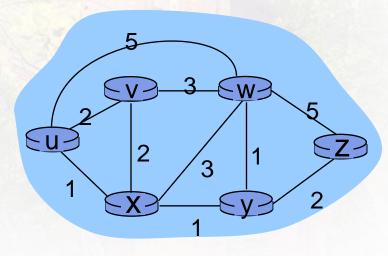

then

$$d_x(y) = \min_{x} \{c(x, y) + d_y(y)\}$$

cost from neighbor v to destination y cost to neighbor v

min taken over all neighbors v of x

Bellman-Ford example

clearly,
$$d_v(z) = 5$$
, $d_x(z) = 3$, $d_w(z) = 3$

B-F equation says:

$$d_{u}(z) = \min \{ c(u,v) + d_{v}(z), \\ c(u,x) + d_{x}(z), \\ c(u,w) + d_{w}(z) \}$$

$$= \min \{ 2 + 5, \\ 1 + 3, \\ 5 + 3 \} = 4$$

node achieving minimum is next hop in shortest path, used in forwarding table

- D_x(y) = estimate of least cost from x to y
 - \blacksquare x maintains distance vector $D_x = [D_x(y): y \in N]$
- node x:
 - knows cost to each neighbor v: c(x,v)
 - maintains its neighbors' distance vectors. For each neighbor v, x maintains

$$D_v = [D_v(y): y \in N]$$

key idea:

- * from time-to-time, each node sends its own distance vector estimate to neighbors
- * when x receives new DV estimate from neighbor, it updates its own DV using B-F equation:

$$D_x(y) \leftarrow min_v\{c(x,v) + D_v(y)\}\$$
 for each node $y \in N$

* under minor, natural conditions, the estimate $D_x(y)$ converge to the actual least cost $d_x(y)$

iterative, asynchronous: each local iteration caused by:

- local link cost change
- DV update message from neighbor

distributed:

- each node notifies neighbors only when its DV changes
 - neighbors then notify their neighbors if necessary

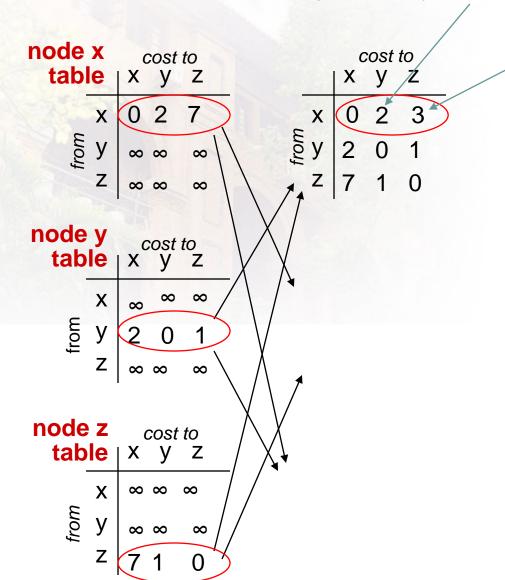

each node:

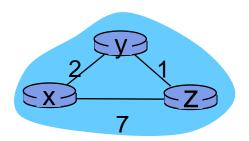

wait for (change in local link cost or msg from neighbor) recompute estimates if DV to any dest has changed, *notify* neighbors

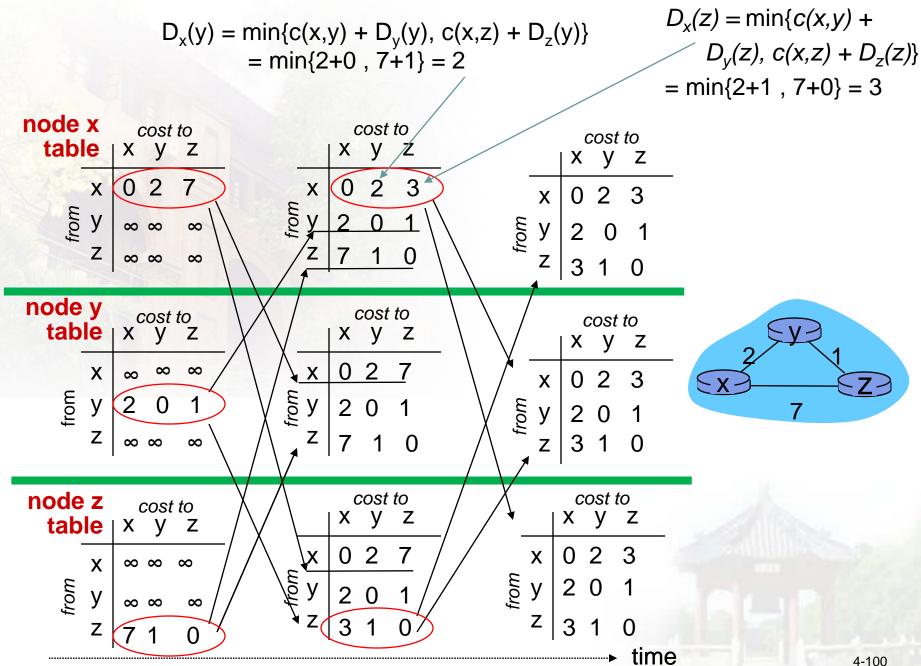

$$D_x(y) = \min\{c(x,y) + D_y(y), c(x,z) + D_z(y)\}$$

= \text{min}\{2+0, 7+1\} = 2

 $D_x(z) = \min\{c(x,y) + D_y(z), c(x,z) + D_z(z)\}$ = $\min\{2+1, 7+0\} = 3$

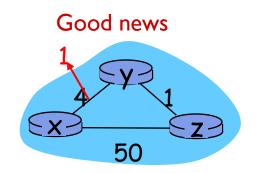

Distance vector: link cost changes

link cost changes:

- node detects local link cost change
- updates routing info, recalculates distance vector
- if DV changes, notify neighbors

"good news travels fast" t_0 : y detects link-cost change, updates its DV, informs its neighbors.

 t_1 : z receives update from y, updates its table, computes new least cost to x, sends its neighbors its DV.

 t_2 : y receives z's update, updates its distance table. Y's least costs do *not* change, so y does *not* send a message to z.

Distance vector: link cost changes

link cost changes:

- node detects local link cost change
- bad news travels slow "count to infinity" problem!
- 44 iterations before algorithm stabilizes: see text

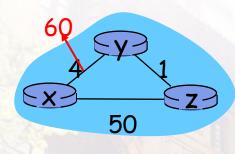

Bad news

poisoned reverse:

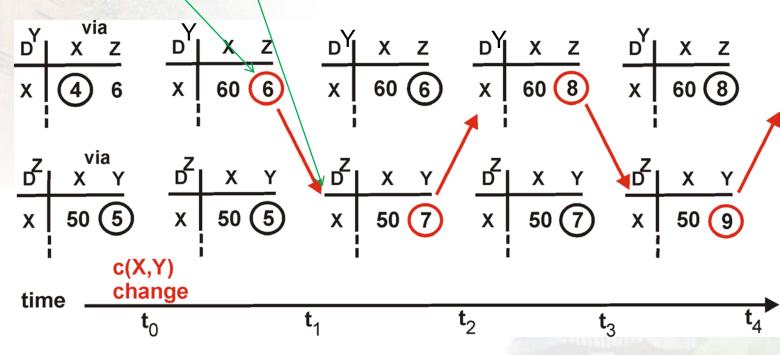

- If Z routes through Y to get to X:
 - Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z)
- will this completely solve count to infinity problem?

Bad news

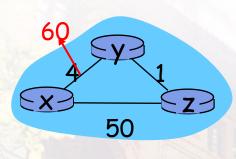

Y's understanding: Dist(From Y to X via Z) = 6

Z's understanding: Dist(From Y to X) = 6

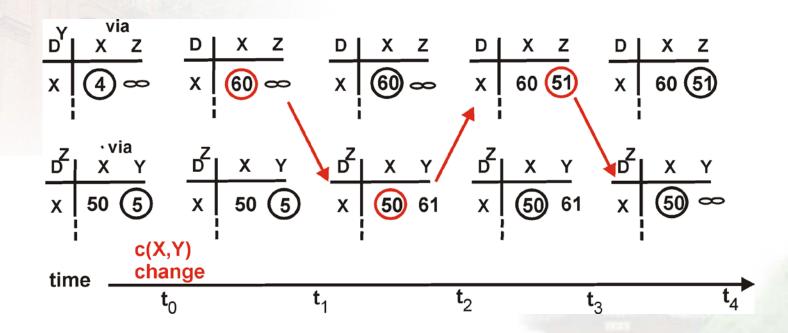

Bad news

If Z routes through Y to get to X:

- Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z)
- will this completely solve count to infinity problem?

关键原因: Z知道自己通过Y到达X,因此如果遇到Y让Z转发给X的,就可以拒绝。

Comparison of LS and DV algorithms

message complexity

- LS: with n nodes, E links, O(nE) msgs sent
- DV: exchange between neighbors only
 - convergence time varies

speed of convergence

- LS: O(n²) algorithm requires O(nE) msgs
 - may have oscillations
- DV: convergence time varies
 - may be routing loops
 - count-to-infinity problem

robustness: what happens if router malfunctions?

LS:

- node can advertise incorrect link cost
- each node computes only its own table

DV:

- DV node can advertise incorrect path cost
- each node's table used by others
 - error propagate thru network

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Hierarchical routing

our routing study thus far - idealization

- * all routers identical
- network "flat"
- ... not true in practice

scale: with 600 million destinations:

- can't store all dest's in routing tables!
- routing table exchange would swamp links!

administrative autonomy

- internet = network of
 networks
- each network admin may want to control routing in its own network

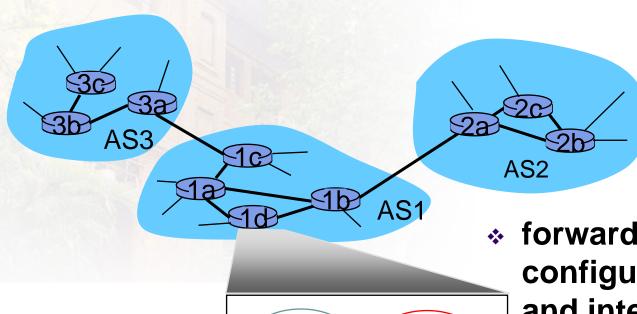

Hierarchical routing

- aggregate routers into regions, "autonomous systems" (AS)
- routers in same AS run same routing protocol
 - "intra-AS" routing protocol
 - routers in different AS can run different intra-AS routing protocol

gateway router:

- at "edge" of its own AS
- has link to router in another AS

Interconnected ASes

Intra-AS
Routing
algorithm

Forwarding
table

 forwarding table configured by both intraand inter-AS routing algorithm

- intra-AS sets entries for internal dests
- inter-AS & intra-AS sets entries for external dests

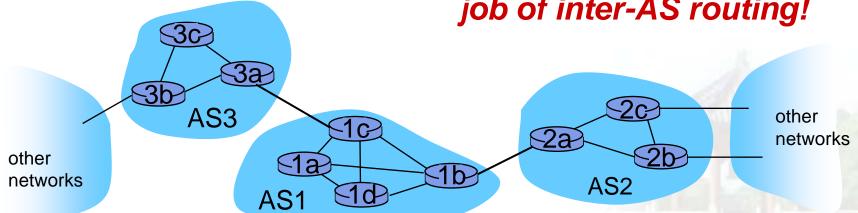

Inter-AS tasks

- suppose router in AS1 receives datagram destined outside of AS1:
 - router should forward packet to gateway router, but which one?

AS1 must:

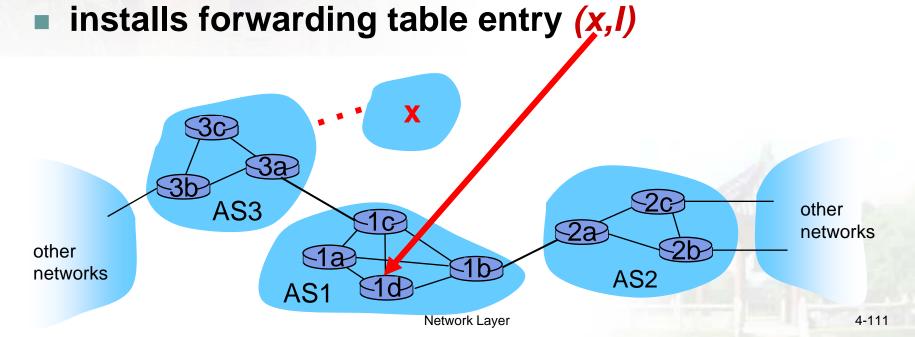

- learn which dests are reachable through **AS2**, which through AS3
- propagate this reachability info to all routers in AS1

job of inter-AS routing!

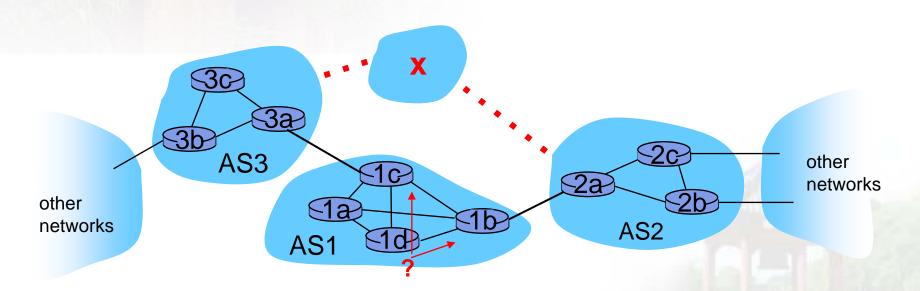

Example: setting forwarding table in router 1d

- suppose AS1 learns (via inter-AS protocol) that subnet x reachable via AS3 (gateway 1c), but not via AS2
 - inter-AS protocol propagates reachability info to all internal routers
- router 1d determines from intra-AS routing info that its interface / is on the least cost path to 1c

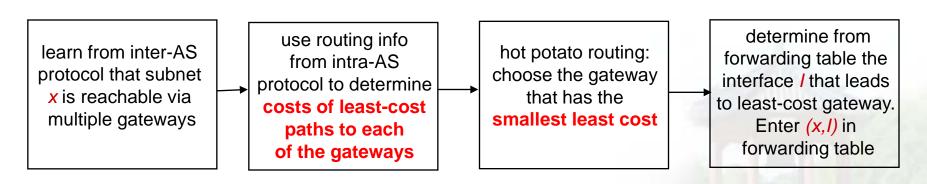

Example: choosing among multiple ASes

- now suppose AS1 learns from inter-AS protocol that subnet x is reachable from AS3 and from AS2.
- to configure forwarding table, router 1d must determine which gateway it should forward packets towards for dest
 - this is also job of inter-AS routing protocol!

Example: choosing among multiple ASes

- now suppose AS1 learns from inter-AS protocol that subnet x is reachable from AS3 and from AS2.
- to configure forwarding table, router 1d must determine towards which gateway it should forward packets for dest
 - this is also job of inter-AS routing protocol!
- hot potato routing: send packet towards closest of two routers.

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

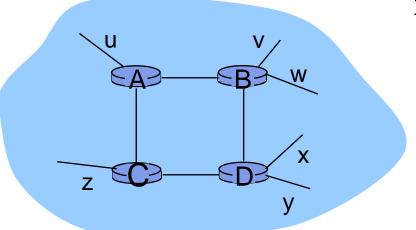

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Intra-AS Routing

- * also known as interior gateway protocols (IGP)
- * most common intra-AS routing protocols:
 - RIP: Routing Information Protocol
 - OSPF: Open Shortest Path First
 - IGRP: Interior Gateway Routing Protocol (Cisco proprietary)

RIP (Routing Information Protocol)

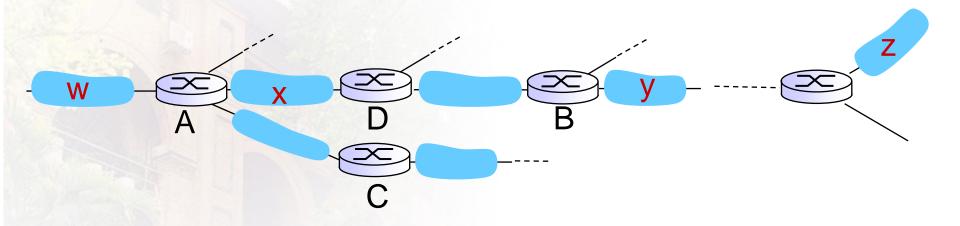

- included in BSD-UNIX distribution in 1982
- distance vector algorithm
 - distance metric: # hops (max = 15 hops), each link has cost 1
 - DVs exchanged with neighbors every 30 sec in response message (aka advertisement)
 - each advertisement: list of up to 25 destination subnets (in IP addressing sense)

from router A to destination subnets:

<u>subnet</u>	<u>hops</u>
u	1
V	2
W	2
X	3
y	3
Z	2

RIP: example

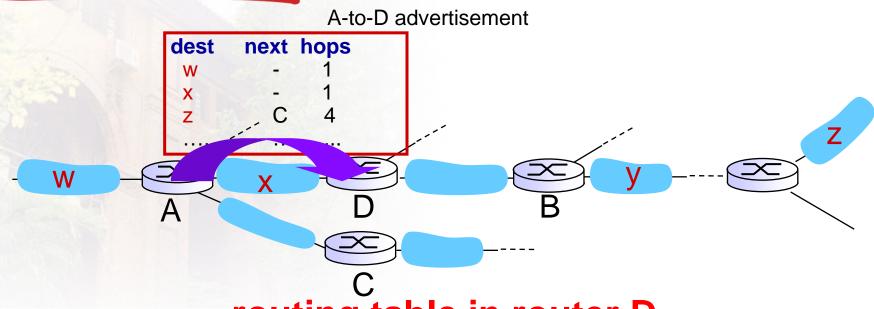

routing table in router D

destination subnet	next router	# hops to dest	
W	Α	2	(D+A) (D+B)
y	В	2	(D+B)
Z	В	7	
X			
			النبيات

4-117

RIP: example

routing table in router D

destination subnet	next router	# hops to dest
W	Α	2
у	В	2
Z	BA	75
X		

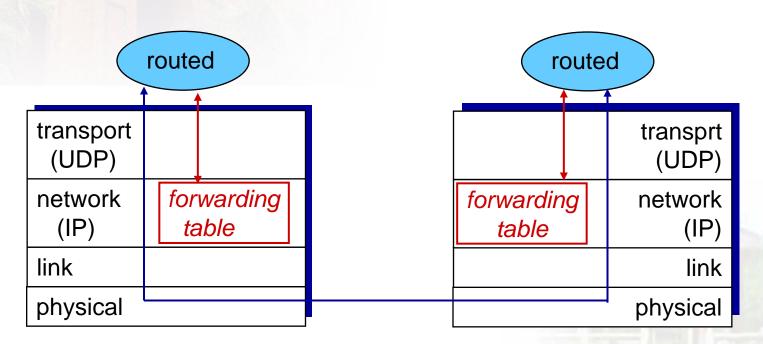

RIP: link failure, recovery

if no advertisement heard after 180 sec --> neighbor/link declared dead

- routes via neighbor invalidated
- new advertisements sent to neighbors
- neighbors in turn send out new advertisements (if tables changed)
- link failure info quickly (?) propagates to entire net
- poison reverse used to prevent ping-pong loops (infinite distance = 16 hops)

RIP table processing

- RIP routing tables managed by applicationlevel process called route-d (daemon)
- advertisements sent in UDP packets, periodically repeated

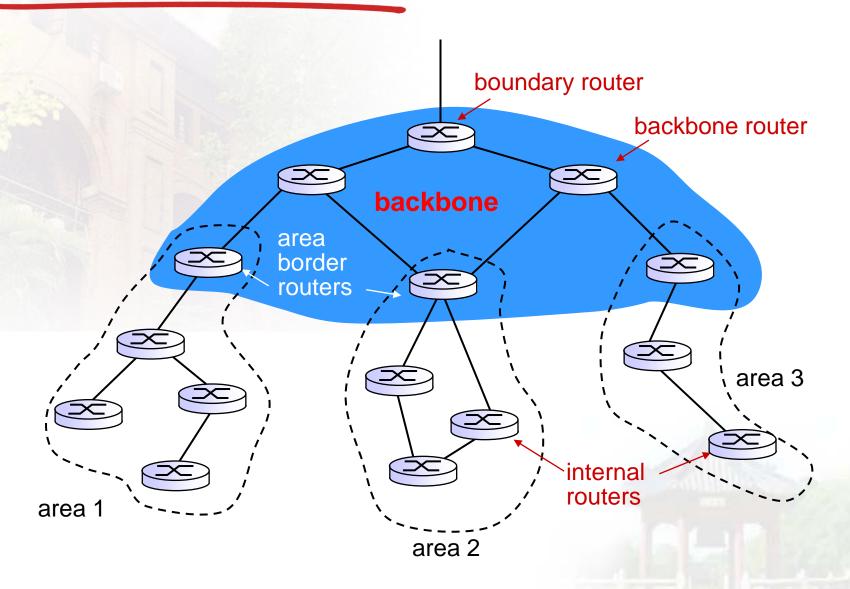

OSPF (Open Shortest Path First)

- "open": publicly available
- uses link state algorithm
 - LS packet dissemination
 - topology map at each node
 - route computation using Dijkstra's algorithm
- OSPF advertisement carries one entry per neighbor
- advertisements flooded to entire AS
 - carried in OSPF messages directly over IP (rather than TCP or UDP
- IS-IS routing protocol: nearly identical to OSPF

OSPF "advanced" features (not in RIP)

- security: all OSPF messages authenticated (to prevent malicious intrusion)
- multiple same-cost paths allowed (only one path in RIP)
- for each link, multiple cost metrics for different TOS (e.g., satellite link cost set "low" for best effort ToS; high for real time ToS)
- integrated uni- and multicast support:
 - Multicast OSPF (MOSPF) uses same topology data base as OSPF
- hierarchical OSPF in large domains.

Hierarchical OSPF

Hierarchical OSPF

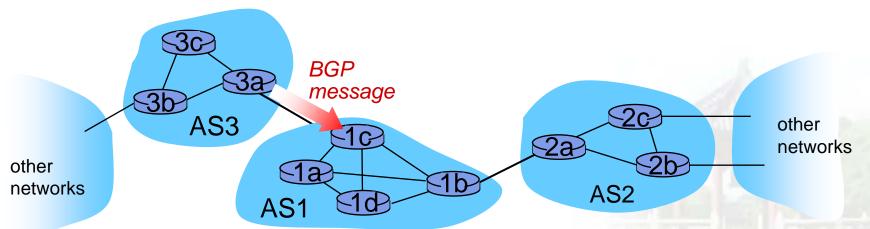

- two-level hierarchy: local area, backbone.
 - link-state advertisements only in area
 - each nodes has detailed area topology; only know direction (shortest path) to nets in other areas.
- area border routers: "summarize" distances to nets in own area, advertise to other Area Border routers.
- backbone routers: run OSPF routing limited to backbone.
- boundary routers: connect to other AS's.

Internet inter-AS routing: BGP

- BGP (Border Gateway Protocol): the de facto inter-domain routing protocol
 - "glue that holds the Internet together"
- BGP provides each AS a means to:
 - eBGP: obtain subnet reachability information from neighboring ASs.
 - iBGP: propagate AS reachability information to all AS-internal routers.
 - determine "good" routes to other networks based on reachability information and policy.
- allows subnet to advertise its existence to rest of Internet: "I am here"

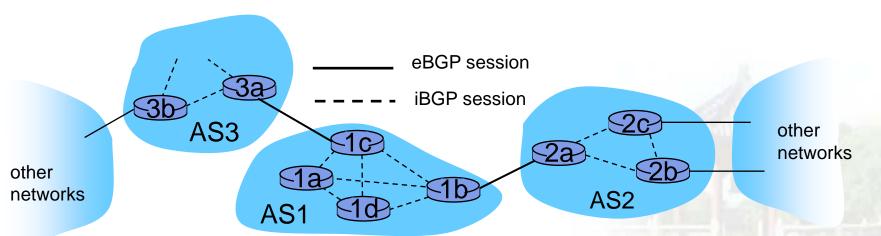

BGP basics

- BGP session: two BGP routers ("peers") exchange BGP messages:
 - advertising paths to different destination network prefixes ("path vector" protocol)
 - exchanged over semi-permanent TCP connections
- when AS3 advertises a prefix to AS1:
 - AS3 promises it will forward datagrams towards that prefix
 - AS3 can aggregate prefixes in its advertisement

BGP basics: distributing path information

- using eBGP session between 3a and 1c, AS3 sends prefix reachability info to AS1.
 - 1c can then use iBGP do distribute new prefix info to all routers in AS1
 - 1b can then re-advertise new reachability info to AS2 over 1b-to-2a eBGP session
- when router learns of new prefix, it creates entry for prefix in its forwarding table.

Path attributes and BGP routes

- advertised prefix includes BGP attributes
 - prefix + attributes = "route"
- two important attributes:
 - AS-PATH: contains ASs through which prefix advertisement has passed: e.g., AS 67, AS 17
 - NEXT-HOP: indicates specific internal-AS router to next-hop AS. (may be multiple links from current AS to next-hop-AS)
- gateway router receiving route advertisement uses import policy to accept/decline
 - e.g., never route through AS x
 - policy-based routing

BGP route selection

- router may learn about more than 1 route to destination AS, selects route based on:
 - 1. local preference value attribute: policy decision
 - 2. shortest AS-PATH
 - closest NEXT-HOP router: hot potato routing
 - 4. additional criteria

BGP messages

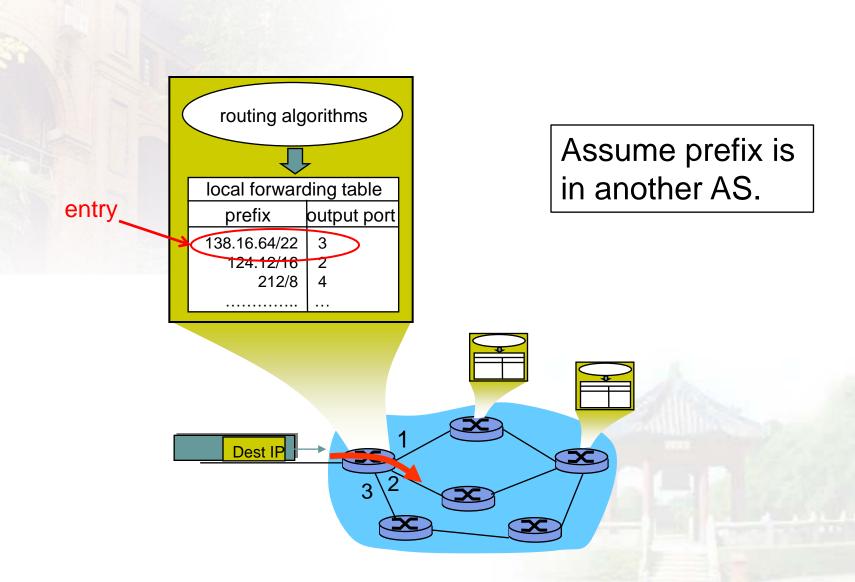

- BGP messages exchanged between peers over TCP connection
- BGP messages:
 - OPEN: opens TCP connection to peer and authenticates sender
 - UPDATE: advertises new path (or withdraws old)
 - KEEPALIVE: keeps connection alive in absence of UPDATES; also ACKs OPEN request
 - NOTIFICATION: reports errors in previous msg; also used to close connection

Putting it Altogether: How Does an Entry Get Into a Router's Forwarding Table?

Answer is complicated!

- Ties together hierarchical routing (Section 4.5.3) with BGP (4.6.3) and OSPF (4.6.2).
- Provides nice overview of BGP!

How does entry get in forwarding table?

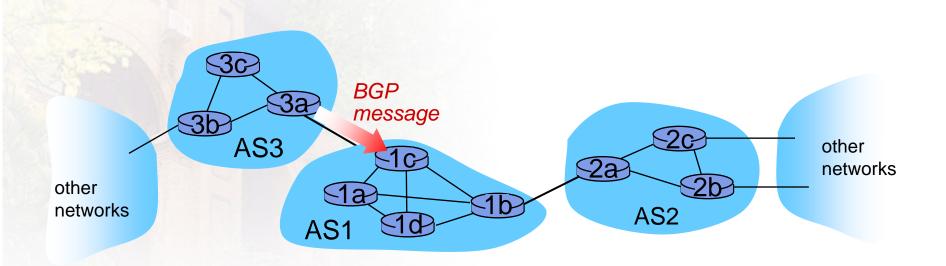

How does entry get in forwarding table?

High-level overview

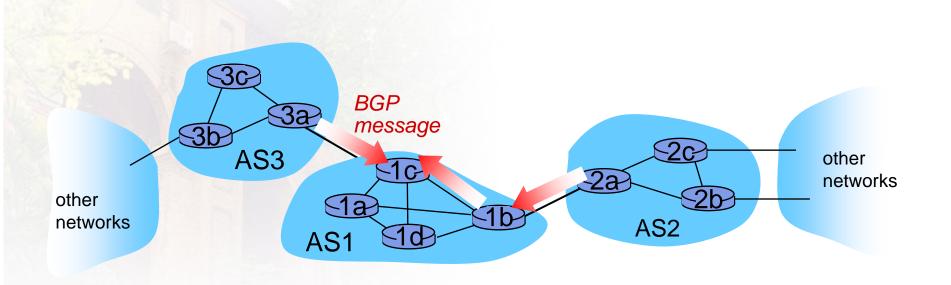

- 1. Router becomes aware of prefix
- 2. Router determines output port for prefix
- 3. Router enters prefix-port in forwarding table

Step1: Router becomes aware of prefix

- BGP message contains "routes"
- "route" is a prefix and attributes: AS-PATH, NEXT-HOP,...
- Example: route:
 - Prefix:138.16.64/22; AS-PATH: AS3 AS131;
 NEXT-HOP: 201.44.13.125

Step2:Router may receive multiple routes

- * Router may receive multiple routes for <u>same</u> prefix
- Has to select one route

Step3:Select best BGP route to prefix

 Router selects route based on shortest AS-PATH

select

- Example:
 - *AS2 AS17 to 138.16.64/22
 - * AS3 AS131 AS201 to 138.16.64/22
- What if there is a tie? We'll come back to that!

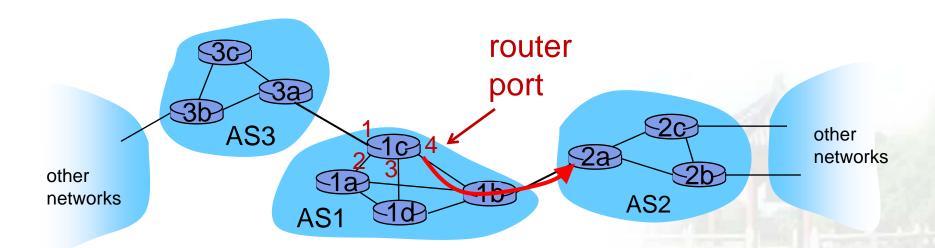

Step4:Find best intra-route to BGP route

- Use selected route's NEXT-HOP attribute
 - Route's NEXT-HOP attribute is the IP address of the router interface that begins the AS PATH.
- Example:
 - * AS-PATH: AS2 AS17; NEXT-HOP: 111.99.86.55
- Router uses OSPF to find shortest path from 1c to 111.99.86.55

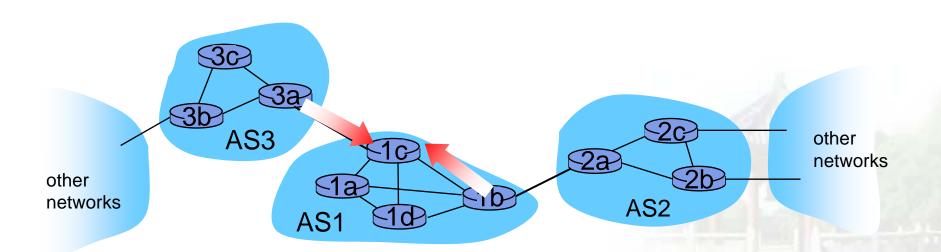

Step5:Router identifies port for route

- Identifies port along the OSPF shortest path
- Adds prefix-port entry to its forwarding table:
 - **(138.16.64/22 , port 4)**

Hot Potato Routing

- Suppose there two or more best inter-routes.
- Then choose route with closest NEXT-HOP
 - Use OSPF to determine which gateway is closest
 - Q: From 1c, chose AS3 AS131 or AS2 AS17?
 - A: route AS3 AS201 since it is closer

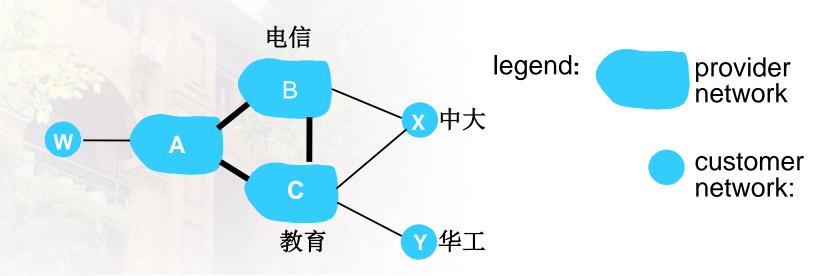

How does entry get in forwarding table?

Summary

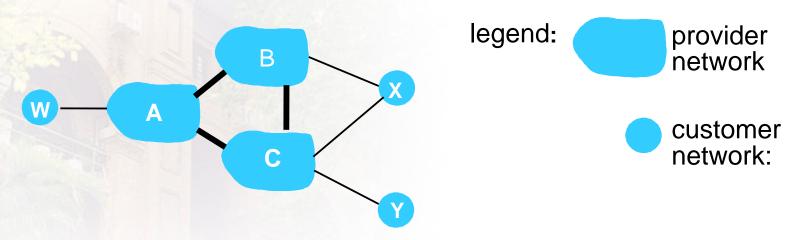

- 1. Router becomes aware of prefix
 - via BGP route advertisements from other routers
- 2. Determine router output port for prefix
 - Use BGP route selection to find best inter-AS route
 - Use OSPF to find best intra-AS route leading to best inter-AS route
 - Router identifies router port for that best route
- 3. Enter prefix-port entry in forwarding table

BGP routing policy (1)

- * A,B,C are provider networks
- X,W,Y are customer (of provider networks)
- * X is dual-homed: attached to two networks
 - X does NOT want to route from B via X to C
 - .. so X will not advertise to B a route to C

BGP routing policy (2)

- * A advertises path AW to B
- B advertises path BAW to X
- Should B advertise path BAW to C?
 - No way! B gets no "revenue" for routing CBAW since neither W nor C are B's customers
 - B wants to force C to route to w via A
 - B wants to route only to/from its customers!

Why different Intra-, Inter-AS routing?

policy:

- inter-AS: admin wants control over how its traffic routed, who routes through its net.
- intra-AS: single admin, so no policy decisions needed

scale:

hierarchical routing saves table size, reduced update traffic

performance:

- intra-AS: can focus on performance
- inter-AS: policy may dominate over performance

Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
 - datagram format
 - IPv4 addressing
 - ICMP
 - IPv6

4.5 routing algorithms

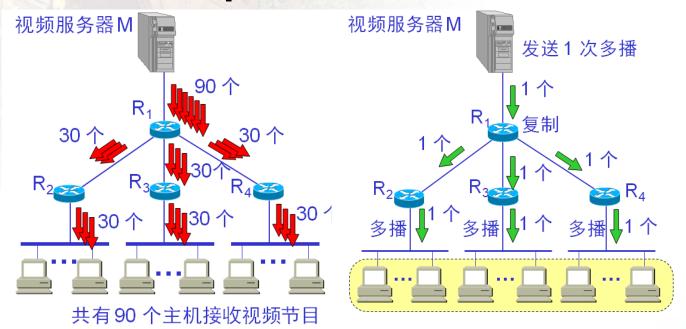

- link state
- distance vector
- hierarchical routing

4.6 routing in the Internet

- RIP
- OSPF
- BGP
- 4.7 broadcast and multicast routing

Broadcast routing

- deliver packets from source to all other nodes
- source duplication is inefficient:

One-to-many communication: video conference, Stock market, news,...

source duplication: how does source (R1) determine recipient addresses (R3,R4)?

IP多播的一些特点

- (1) 多播使用组地址—— IP 使用 D 类地址支持多播。多播地址只能用于目的地址,而不能用于源地址。
- (2) 永久组地址——由因特网号码指派管理局 IANA 负责指派。
- (3) 动态的组成员
- (4) 使用硬件进行多播

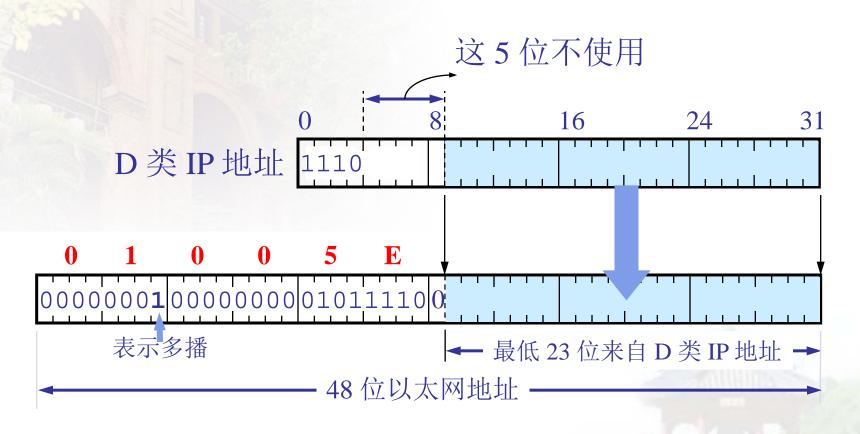

在局域网上进行硬件多播

- 因特网号码指派管理局 IANA 拥有的以太网地址块的高 24 位为 00-00-5E。
- 因此 TCP/IP 协议使用的以太网多播地址块的范围
 是:从 00-00-5E-00-00

到 00-00-5E-FF-FF

• D类 IP 地址可供分配的有 28 位,在这 28 位中的前 5 位不能用来构成以太网硬件地址。

D类IP地址 与以太网多播地址的映射关系

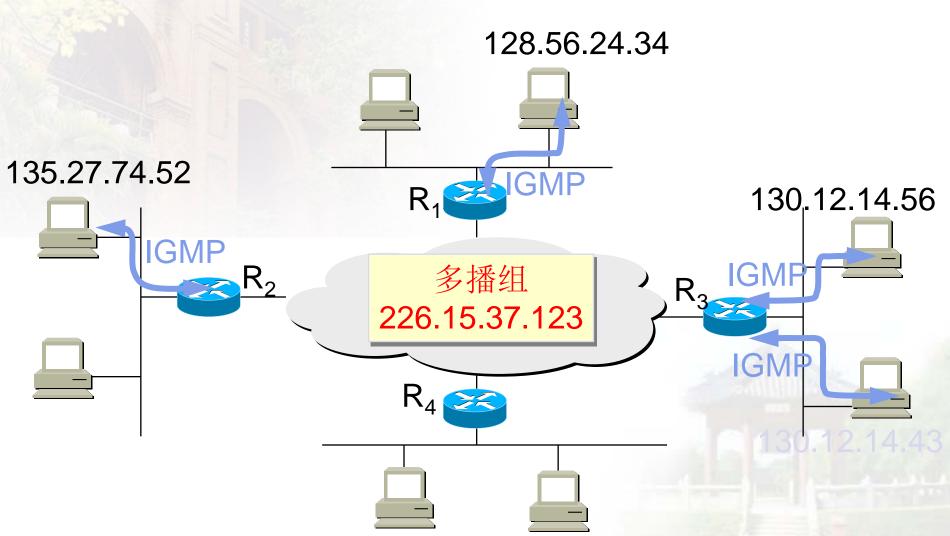

网际组管理协议 IGMP 和多播路由选择协议

1. IP多播需要两种协议

- 为了使路由器知道多播组成员的信息,需要利用网际组管理协议 IGMP (Internet Group Management Protocol)。
- 连接在局域网上的多播路由器还必须和因特网上的其他多播路由器协同工作,以便把多播数据报用最小代价传送给所有的组成员。这就需要使用多播路由选择协议。

IGMP 使多播路由器 知道多播组成员信息

IGMP 的本地使用范围

- IGMP 并非在因特网范围内对所有多播组成员进行管理的协议。
- IGMP 不知道 IP 多播组包含的成员数,也不知道这些成员都分布在哪些网络上。
- IGMP 协议是让连接在本地局域网上的多播路由器知道本局域网上是否有主机(严格讲,是主机上的某个进程)参加或退出了某个多播组。

多播路由选择协议比单播路由选择协议复杂得多

- 多播转发必须动态地适应多播组成员的变化(这时网络拓扑并未发生变化)。请注意,单播路由选择通常是在网络拓扑发生变化时才需要更新路由。
- 多播路由器在转发多播数据报时,不能仅仅根据多播数据报中的目的地址,而是还要考虑这个多播数据报从什么地方来和要到什么地方去。
- 多播数据报可以由没有加入多播组的主机发出,也可以通过没有组成员接入的网络。

2. 网际组管理协议 IGMP

- 1989 年公布的 RFC 1112 (IGMPv1) 早已成 为了因特网的标准协议。
- 1997年公布的 RFC 2236 (IGMPv2, 建议标准) 对 IGMPv1 进行了更新。
- 2002年10月公布了RFC3376(IGMPv3,建 议标准),宣布RFC2236(IGMPv2)是陈旧的。

IGMP 是整个网际协议 IP 的一个组成部分

- •和ICMP相似,IGMP使用IP数据报传递其报文(即IGMP报文加上IP首部构成IP数据报),但它也向IP提供服务。
- 因此,我们不把 IGMP 看成是一个单独的协议, 而是属于整个网际协议 IP 的一个组成部分。

IGMP 可分为两个阶段

第一阶段: 当某个主机加入新的多播组时,该主机应向多播组的多播地址发送IGMP 报文,声明自己要成为该组的成员。本地的多播路由器收到 IGMP 报文后,将组成员关系转发给因特网上的其他多播路由器。

IGMP 可分为两个阶段

- 第二阶段:因为组成员关系是动态的,因此本地多播路由器要周期性地探询本地局域网上的主机,以便知道这些主机是否还继续是组的成员。
- 只要对某个组有一个主机响应,那么多播路由器就认为这个组是活跃的。
- 但一个组在经过几次的探询后仍然没有一个主机响应,则不再将该组的成员关系转发给其他的多播路由器。

IGMP 采用的一些具体措施

- 在主机和多播路由器之间的所有通信都是使用 IP 多播。
- 多播路由器在探询组成员关系时,只需要对所有的组发送一个请求信息的询问报文,而不需要对每一个组发送一个询问报文。默认的询问速率是每 125 秒发送一次。
- 当同一个网络上连接有几个多播路由器时,它们能够迅速和有效地选择其中的一个来探询主机的成员关系。

IGMP 采用的一些具体措施(续)

- 在 IGMP 的询问报文中有一个数值 N, 它指明一个最长响应时间(默认值为 10秒)。当收到询问时,主机在 0 到 N 之间随机选择发送响应所需经过的时延。对应于最小时延的响应最先发送。
- 同一个组内的每一个主机都要监听响应,只要 有本组的其他主机先发送了响应,自己就可以 不再发送响应了。

3. 多播路由选择

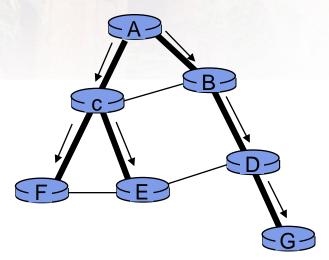

- 多播路由选择协议尚未标准化。
- 一个多播组中的成员是动态变化的,随时会有主机加入或离开这个多播组。
- 多播路由选择实际上就是要找出以源主机为根结点的多播转发树。
- 在多播转发树上的路由器不会收到重复的多播数据报。
- 对不同的多播组对应于不同的多播转发树。同一个多播组,对不同的源点也会有不同的多播转发树。

In-network duplication

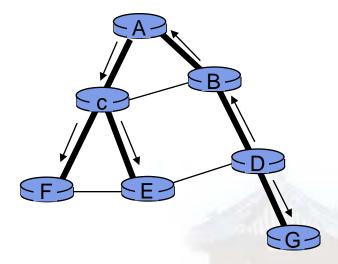

- flooding: when node receives broadcast packet, sends copy to all neighbors
 - problems: cycles & broadcast storm
- controlled flooding: node only broadcasts pkt if it hasn't broadcast same packet before
 - node keeps track of packet ids already broadacsted
 - or reverse path forwarding (RPF): only forward packet if it arrived on shortest path between node and source
- spanning tree:
 - no redundant packets received by any node

Spanning tree

- first construct a spanning tree
- nodes then forward/make copies only along spanning tree

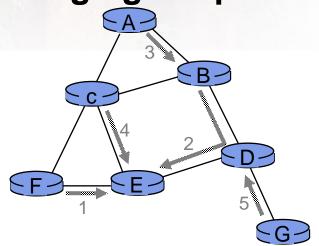

(a) broadcast initiated at A

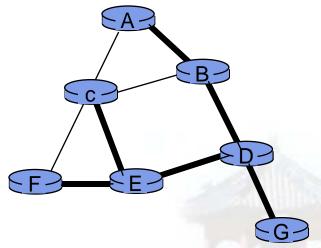

(b) broadcast initiated at D

Spanning tree: creation

- center node
- each node sends unicast join message to center node
 - message forwarded until it arrives at a node already belonging to spanning tree

(a) stepwise construction of spanning tree (center: E)

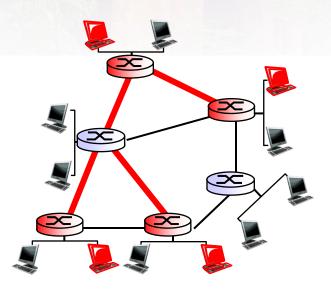

(b) constructed spanning tree

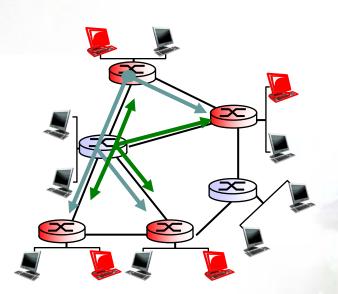

Multicast routing: problem statement

goal: find a tree (or trees) connecting routers having local meast group members

- * tree: not all paths between routers used
- * shared-tree: same tree used by all group members
 - * source-based: different tree from each sender to rcvrs

shared tree

source-based trees

legend

group member

not group member

router with a group member

router without group member

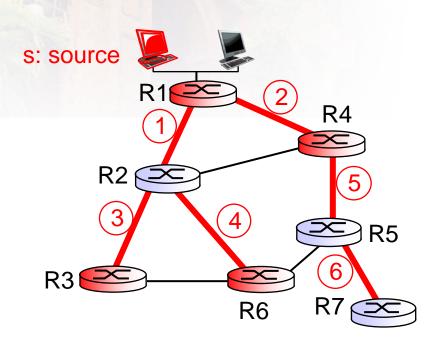

Approaches for building mcast trees

approaches:

- source-based tree: one tree per source
 - shortest path trees
 - reverse path forwarding
- * group-shared tree: group uses one tree
 - minimal spanning (Steiner)
 - center-based trees
 - ...we first look at basic approaches, then specific protocols adopting these approaches

Shortest path tree

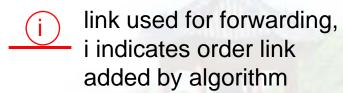

- mcast forwarding tree: tree of shortest path routes from source to all receivers
 - Dijkstra's algorithm

LEGEND

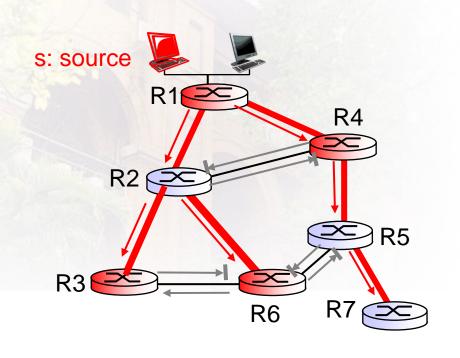

Reverse path forwarding

- rely on router's knowledge of unicast shortest path from it to sender
- each router has simple forwarding behavior:

if (mcast datagram received on incoming link on shortest path back to center)then flood datagram onto all outgoing linkselse ignore datagram

Reverse path forwarding: example

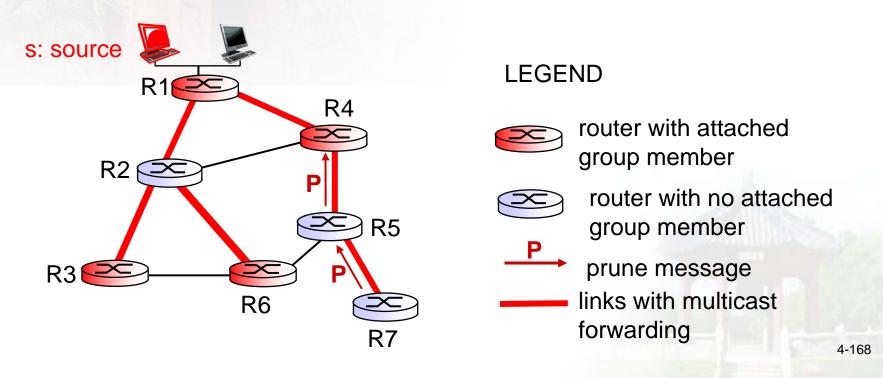

LEGEND

- router with no attached group member
- datagram will be forwarded
- → I datagram will not be forwarded
- result is a source-specific reverse SPT
 - may be a bad choice with asymmetric links

Reverse path forwarding: pruning

- forwarding tree contains subtrees with no mcast group members
 - no need to forward datagrams down subtree
 - "prune" msgs sent upstream by router with no downstream group members

Chapter 4: done!

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- **4.4 IP: Internet Protocol**
 - datagram format, IPv4 addressing, ICMP, IPv6

4.5 routing algorithms

- link state, distance vector, hierarchical routing
- 4.6 routing in the Internet
 - RIP, OSPF, BGP
- 4.7 broadcast and multicast routing
- understand principles behind network layer services:
 - network layer service models, forwarding versus routing how a router works, routing (path selection), broadcast, multicast
- instantiation, implementation in the Internet

Quiz for Chapter 4

- Brief describe the A Link-State Routing Algorithm procedure, and give a practical example of Internet protocol using it.
- What's the difference of source-based tree and group-shared tree? What's the approaches for building these meast trees?
- What's BGP? How it works?
- What's the difference of broadcast vs multicast routing?
- What's CIDR?
- Please compare the LS and DV algorithms

- What's the difference of Datagram or VC network? Use Internet and ATM as examples
- What's DHCP? Brief describe how it works.
- How does the Graph theory apply to computer networks? Point out 2 graph examples in computer networks.
- What's Head-of-the-Line (HOL) blocking? Where does it occur?
- What's the meaning of hierarchical addressing: route aggregation?
- Give the fragmentation of a IP datagram, with size of 5000 bytes and the MTU = 1500 bytes.
- What's the changes (or advantages) of IPv6, compare to IPv4?

- What's the key network-layer functions
- What's longest prefix matching? Give an example.
- What's NAT, and how it works?
- How to solve the NAT traversal problem? Give 2 solutions
- What service model for "channel" transporting datagrams from sender to receiver?
- What's the difference of network and transport layer connection service?
- What's PIM, how does PIM sparse mode work?
- What's RPF, and how does it work?

- Talk about the three types of switching fabrics inside routers, focus on their advantages and disadvantages
- How does Traceroute program works?
- Talk about the Transition from IPv4 to IPv6.
 How will the network operate with mixed IPv4 and IPv6 routers?
- What does a VC consist of?
- What's RIP? What algorithm does it use and how it works?
- Why different Intra- and Inter-AS routing?

Task-2: virtual routing (Application-layer routing)

- self-organized routing
 - Select a virtual topo for members' computers
 - Build virtual connection between computers according to the virtual topo, define the cost of links;
 - Each computer acts as both client and router.
 - Each computer exchanges and updates routing table periodically.
 - A computer can send message to other computers,

Hint:

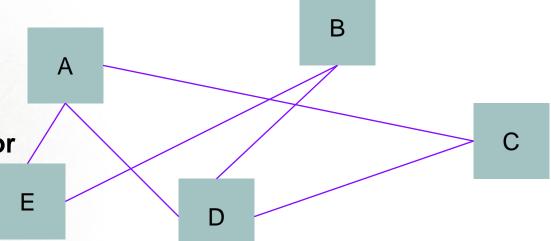

- >IP-in-IP (IP-layer virtual routing) or
- >use sock directly (Application-layer routing)
- >Use TCP or UDP

Step 1:

➤ Design the virtual topo (link cost)

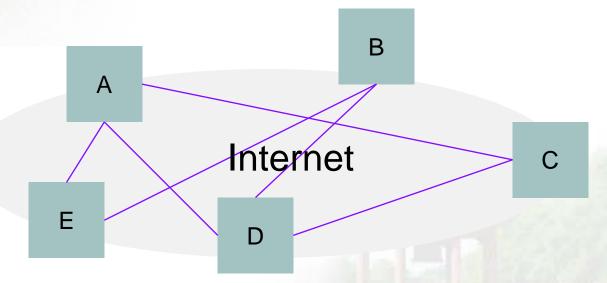

Each node has two ports for receiving and sending:

Prt_I, Prt_O.

Step 2:

Build the virtual Topo over Internet, define the cost of links; exchange the routing information periodically

Step 3:

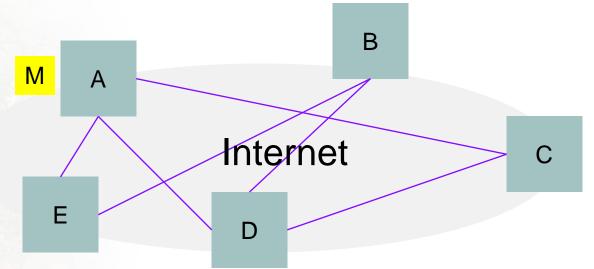

Simulate the routing and forwarding. For example

A sends M to B. Which path is better?

$$A \rightarrow E \rightarrow B$$
? or

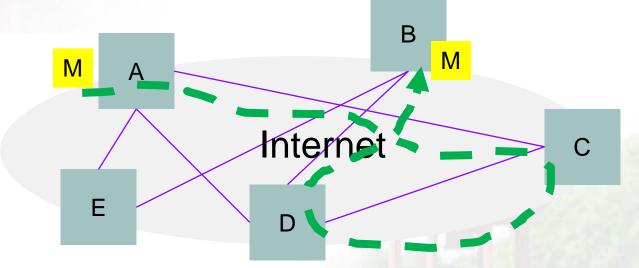

$$A \rightarrow D \rightarrow B$$
?

$$A \rightarrow C \rightarrow D \rightarrow B$$
?

Step 4:

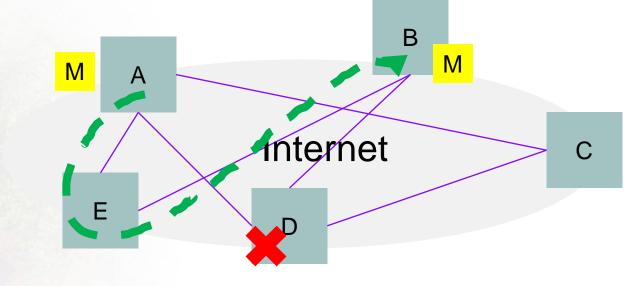

Transmit data M via the best path, e.g., $A \rightarrow C \rightarrow D \rightarrow B$

Please try different topo and different routing algorithms (LS & DV).

Step 5:

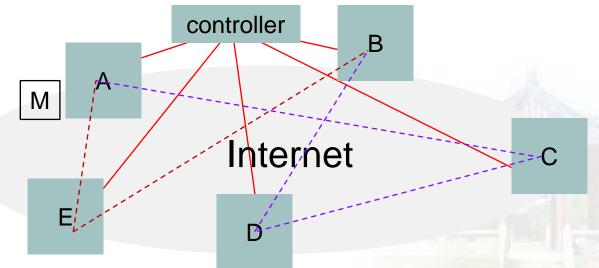

A node is down. e.g., D

Please try different topo and different routing algorithms (LS & DV).

- Task-2: virtual routing
 - centralized routing
 - Like the above self-organized routing
 - Controller determines and distributes routing policy (routing table) to each member

Example: A sends M to B. Which path is better? A \rightarrow E \rightarrow B? or A \rightarrow C \rightarrow D \rightarrow B?

Submit

- PPTs + demo video
- Source code (and the compiled executable files)
- The project report documents (including introduction, design, setup and deploy, and result, project management records)
- The individual report of each team members (your contributions, and anything else you want to talk about)
- votes of the top 5 teams (based on their presentations and your observations, give comments of 2-3 sentences)
- A list that shows each member's contribution and grade.

Put all file into a package and name it as:

A_B_C.rar,

A: the student ID of group leader;

B: the name of group leader;

C: task1 or task2

example: 1500001_张三_task1.rar

Group leader submit it to the given FTP server.

Basic points

- Protocol design. (10 points)
- Finish basic function correctly (w/o error). (60 points)
- On time (WEEK 15). (10 points)
- Documents, codes, presentation. (20 points)
- votes
- in-group assessment
